What is the scalar singlet model?

- Ultra-minimal dark matter model (Silveira & Zee, PLB 1985)
- 1 new scalar particle S, SM gauge singlet

  $\rightarrow$ 4 new (renormalizable) Lagrangian terms not forbidden by any symmetries:

$$\mathcal{L}_S = -\frac{\mu_S^2}{2}S^2 - \frac{\lambda_{hs}}{2}S^2 H^\dagger H - \frac{1}{2}\partial_\mu S \partial^\mu S - \frac{\lambda_S}{4}\lambda_S S^4 \quad (1)$$

- Impose Z_2 symmetry to make S stable
  $\rightarrow$ S^3 and $SH^\dagger H$ terms disallowed

What is the scalar singlet model?

- 1 new scalar particle S, SM gauge singlet

  $\rightarrow$ 4 new (renormalizable) Lagrangian terms not forbidden by any symmetries:

$$\mathcal{L}_S = -\frac{\mu_S^2}{2} S^2 - \frac{\lambda_{hs}}{2} S^2 H^\dagger H - \frac{1}{2}\partial_\mu S \partial^\mu S - \frac{\lambda_S}{4}\lambda_S S^4 \qquad (1)$$

- Impose Z_2 symmetry to make S stable
  $\rightarrow$ S^3 and $SH^\dagger H$ terms disallowed
- $\partial_\mu S \partial^\mu S$ = S kinetic term, $\lambda_S S^4$ = S self-interaction

What is the scalar singlet model?

- Ultra-minimal dark matter model (Silveira & Zee, PLB 1985)
- 1 new scalar particle S, SM gauge singlet

  $\rightarrow$ 4 new (renormalizable) Lagrangian terms not forbidden by any symmetries:

$$\mathcal{L}_S = -\frac{\mu_S^2}{2} S^2 - \frac{\lambda_{hs}}{2} S^2 H^\dagger H - \frac{1}{2}\partial_\mu S \partial^\mu S - \frac{\lambda_S}{4} \lambda_S S^4 \quad (1)$$

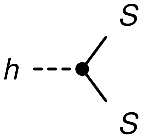
- Impose Z_2 symmetry to make S stable
  $\rightarrow$ S^3 and $SH^\dagger H$ terms disallowed
- $\partial_\mu S \partial^\mu S$ = S kinetic term, $\lambda_S S^4$ = S self-interaction
  $\rightarrow$ So long as $\lambda_S \lesssim 1$ (to remain perturbative), only $\mu_S^2 S^2$ and $\lambda_{hs} S^2 H^\dagger H$ matter for phenomenology

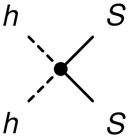
Consequences

After H gets a VEV v_0 during electroweak symmetry-breaking, $\lambda_{hs} S^2 H^\dagger H$ induces hSS and $hhSS$ terms:

$$\mathcal{L}_{S^2|H|^2} \rightarrow O_{hSS} + O_{hhSS} = -\frac{\lambda_{hs} v_0}{2} hSS - \frac{\lambda_{hs}}{4} hhSS \qquad (2)$$

Introduces two new interaction vertices:





S gets mass contributions from bare term $\mu_S^2 S^2$ and new SS term also induced by $\lambda_{hs} S^2 H^\dagger H$:

$$m_S = \sqrt{\mu_S^2 + \frac{\lambda_{hs} v_0^2}{2}} \qquad (3)$$

Advantages

Question

Why is the scalar singlet model attractive?

Advantages

Question

Why is the scalar singlet model attractive?

Answers

- Occam's razor: super-simple, just one singlet scalar and a Z_2 symmetry
- 2 parameters only: λ_{hs}, m_S (or trade for μ_S if you prefer)
- All phenomenology fully calculable, some extremely straightforwardly
- Predictive and very testable

Advantages

Question

Can it solve the hierarchy problem / give me 130 GeV lines / low-mass DM / make my lunch?

Advantages

Question

Can it solve the hierarchy problem / give me 130 GeV lines / low-mass DM / make my lunch?

Answers

Not really. . .

- any hierarchy ‘solution’ would require fine-tuning and probably not hold at higher orders anyway
- 130 GeV line requires additional charged scalar
- Low-mass direct detection is conceivable, but parameters are ruled out (more later)
- Electroweak baryogenesis works, but not with S as all DM (more later)

Phenomenology

Plenty of phenomenological studies over the years...

- Pre-LHC investigations of collider and dark matter detection prospects
  (e.g. McDonald hep-ph/0106249, Burgess et al. hep-ph/0011335, Patt & Wilczek hep-ph/0605188, Barger et al. 0706.4311, 1008.1796)
- As an explanation for DAMA/CoGeNT/CRESST
  (Andreas et al. 0808.0255, 1003.2595, Tytgat 1012.0576)
- Indirect detection prospects
  (Yaguna 0810.4267, Goudelis et al. 0909.2799, Arina & Tytgat 1007.2765)
- As a way to achieve baryogenesis
  (Profumo et al. 0705.2425, Barger et al. 0811.0393, Cline & Kainulainen 1210.4196)
- Impacts of early LHC searches, XENON-100
  (e.g. Mambrini 1108.0671, Djouadi et al. 1205.3169)

Phenomenology

Question

Why the update?

Phenomenology

Question

Why the update?

Answers

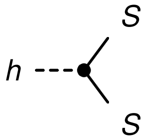
- Include 125 GeV Higgs
- Update to new LHC limits
- Update to new XENON100 limits
- Add *Fermi* dwarf and CMB limits (best ID limits available)
- Treat models with sub-dominant relic densities consistently
- Higgs-nucleon coupling now much better understood from lattice calculations
- Use full thermal-average $\langle\sigma v\rangle$ for relic density

Outline

1. Background
2. Updated constraints
   - LHC: Invisible Higgs width
   - Relic density and indirect detection
   - Direct detection

Dude, where's my Higgs?

If S is light enough, the Higgs decay $h \to SS$ is kinematically allowed:



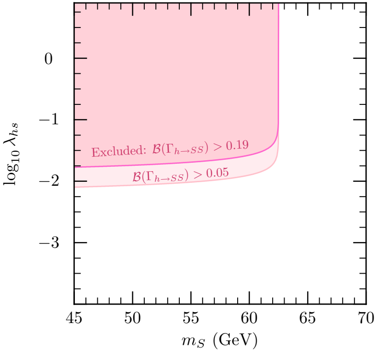
with rate:

$$\Gamma_{h\to SS} = \frac{\lambda_{hs}^2 v_0^2}{32\pi m_h^2}\left(m_h^2 - 4m_S^2\right)^{1/2} \quad (4)$$

- Higgs production rates (e.g. via gg fusion, vector boson fusion) can be compared to observed h decay rates (e.g. $\gamma\gamma$, $b\bar{b}$, etc) to test for missing decays
- Latest 95% CL combined LHC+Tevatron limit across all production and decay channels is $BF_{SS} < 19\%$ (Belanger et al. 1306.2941)

Constraints

Resulting LHC+Tevatron limits:



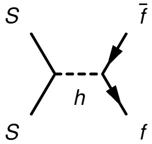
300 fb^{-1} 14 TeV LHC will manage BF limit of 5% (Peskin, arXiv:1207.2516)

Outline

1. Background
2. Updated constraints
   - LHC: Invisible Higgs width
   - Relic density and indirect detection
   - Direct detection

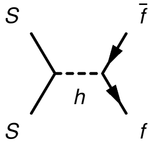
Annihilation Channels

$SS \to f\bar{f}$:

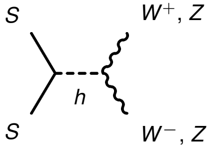


Annihilation Channels

$SS \to f\bar{f}$:

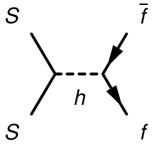


$SS \to V\bar{V}$:

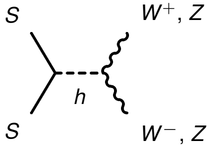


Annihilation Channels

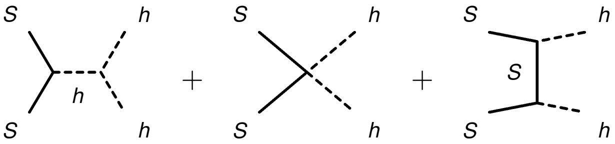
$SS \to f\bar{f}$:



$SS \to V\bar{V}$:

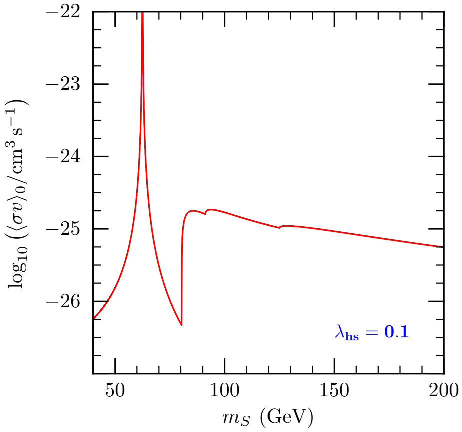


$SS \to hh$:



Annihilation cross-section

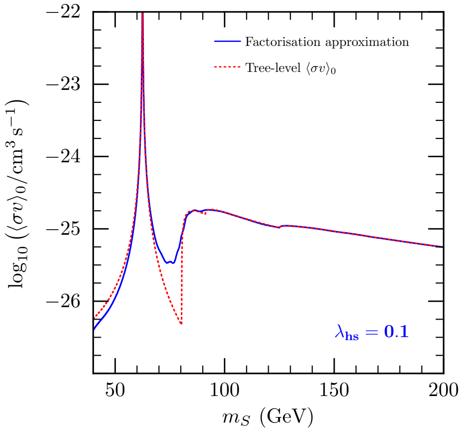
Resulting $\langle \sigma v \rangle_0$:



- Higgs resonance: $m_S \sim m_h/2 = 62.5\,\mathrm{GeV}$
- W, Z thresholds: 4-body final states from $SS \to V^* \bar{V}^* \to f\bar{f}\ f\bar{f}$ become significant just below $m_{W,Z}$

Annihilation cross-section

Resulting $\langle \sigma v \rangle_0$:

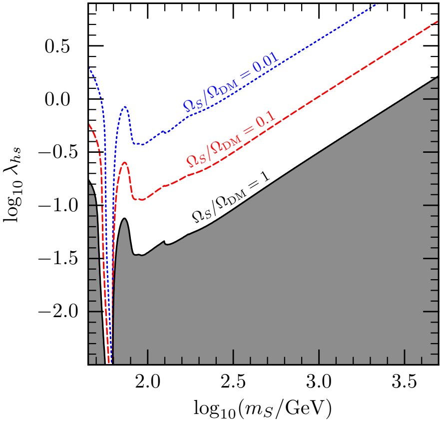


→ better to factor non-*hh* channels into *SSh* fusion part × full Higgs decay width Γ_h to all SM particles:

$$\begin{aligned}\langle \sigma v \rangle_0 &= \langle \sigma v \rangle_{0,hh} + \langle \sigma v \rangle_{0,\mathrm{others}} \\ &= \langle \sigma v \rangle_{0,hh} + \\ &\quad \frac{\lambda_{hs}^2 v_0^2 \Gamma_h}{m_S\left[(4m_S^2 - m_h^2)^2 + m_h^2 \Gamma_h^2\right]}\end{aligned} \tag{5}$$

Relic density

Resulting relic densities:



- When $m_S \gtrsim m_h/2$: OK to just get relic density estimate direct from $\langle\sigma v\rangle_0$

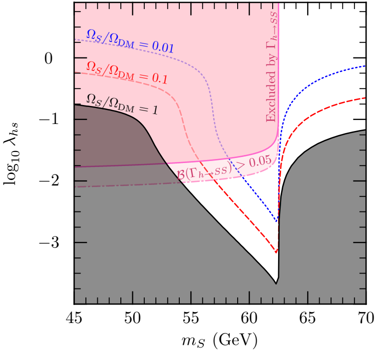
  (a la Steigman et al. 1204.3622)

- When $m_S < h/2$: must include thermal effects $\rightarrow$ relic density in this region from explicit freeze out calculation (just assuming instantaneous thermalisation – gives a conservative limit)

Relic density

Together with Higgs invisible width, rules out all models with $m_S < 53\,\text{GeV}$

$\Longrightarrow$ DAMA/CoGeNT/CRESST not seeing scalar singlet DM



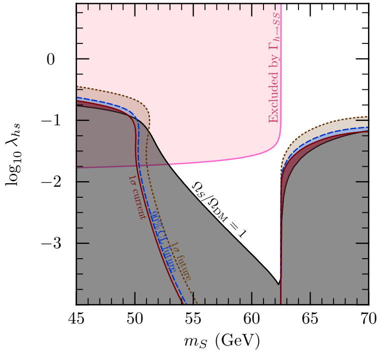
Indirect Detection Limits

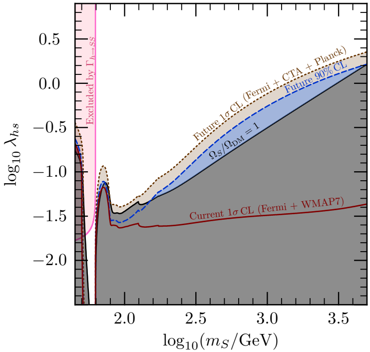
1. *Fermi*-LAT 3-year combined dwarf gamma-ray limits
   (Geringer-Sameth & Koushiappas 1108.2914, Fermi-LAT Collab 1108.3546)
   - Implemented from *full set of CLs* on gamma-ray flux particle physics parameter $\Phi_{\rm PP}$ (1108.2914; kindly provided by Alex Geringer-Sameth)
2. CMB constraints on energy injection (WMAP7 / Planck polarisation)
   - Implemented with tabulated likelihoods for all SM final states (Cline & PS 1301.5908)

$\rightarrow$ Model-by-model *Fermi* + CMB combination of limits from all final states, according to actual branching fractions as each $\{m_S, \lambda_{hs}\}$.

Indirect Detection Limits

Resulting ID limits:



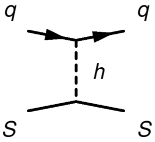


- Current ID reveals slight tension at $\geq 1\sigma$ level in small parts of parameter space, but not much better than that
- Future searches (*Fermi* 10 yr, 20 dwarfs + Planck pol. + CTA 500 hr GC) will exclude more at 90% CL; yet more will be in $\gtrsim 1\sigma$ tension.

Outline

1 Background
2 Updated constraints
- LHC: Invisible Higgs width
- Relic density and indirect detection
- Direct detection

Higgs portal interactions give spin-independent nuclear scattering via *t*-channel Higgs exchange:

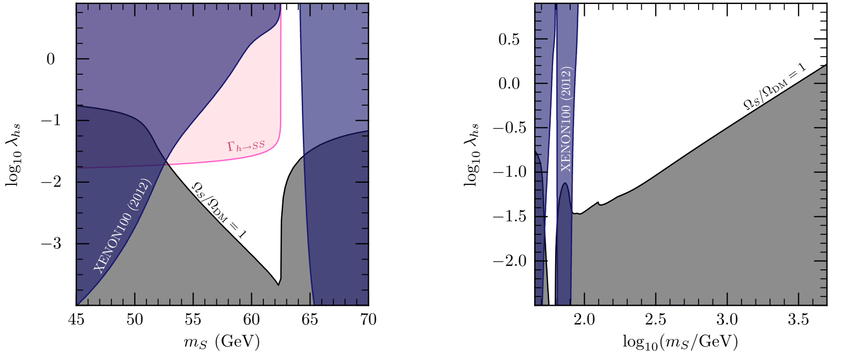


Cross-section in terms of S-N reduced mass μ_N is quite simple:

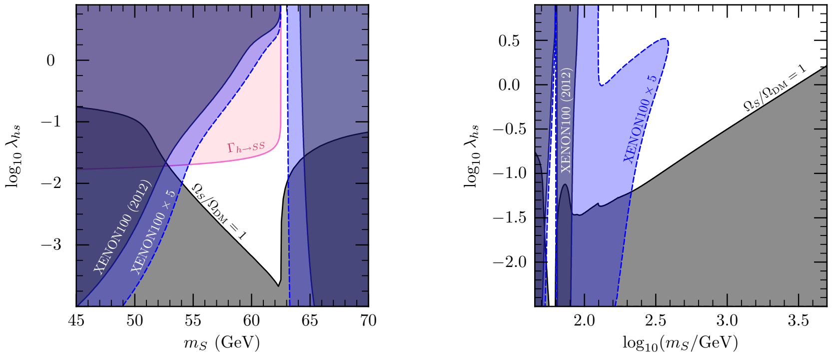
$$\sigma_{\mathrm{SI},N} = \frac{\lambda_{hs}^2 f_N^2 \mu_N^2 m_N^2}{4\pi m_h^4 m_S^2}. \tag{6}$$

- Pion nuclear sigma uncertainty recently reduced (ChPT, lattice vals ↑ to ∼60 MeV – matches experiment)
  → strange quark content of nucleons now not as important
  → Higgs-N effective coupling now $f_N \sim 0.345 \pm 0.02$
- Following results just use standard Maxwellian halo.

Resulting direct limits:

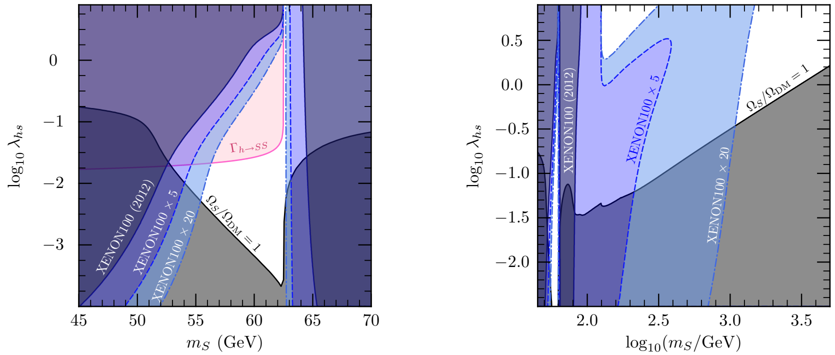


Resulting direct limits:



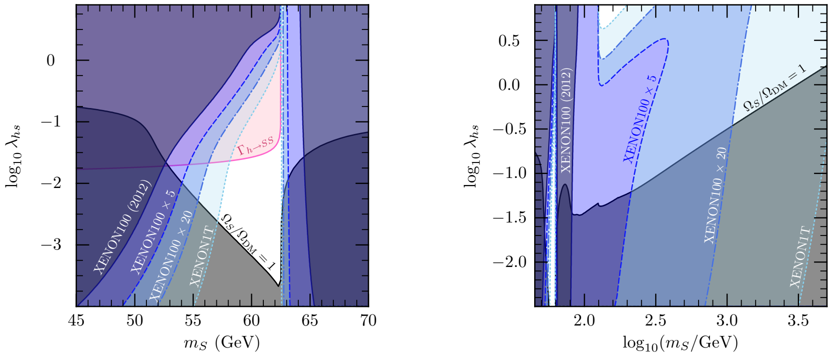
- Future direct detection experiments (LUX, XENON-1T, DARWIN) will probe most of the parameter space. . .
- . . . yet a small window at $m_S \sim 60$ GeV will remain viable.

Resulting direct limits:



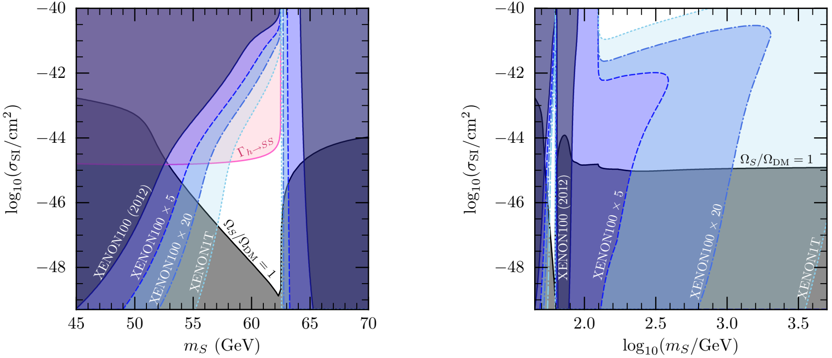
- Future direct detection experiments (LUX, XENON-1T, DARWIN) will probe most of the parameter space. . .
- . . . yet a small window at $m_S \sim 60$ GeV will remain viable.

Resulting direct limits:



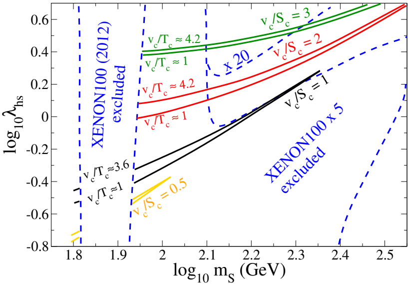
- Future direct detection experiments (LUX, XENON-1T, DARWIN) will probe most of the parameter space. . .
- . . . yet a small window at $m_S \sim 60\,\mathrm{GeV}$ will remain viable.

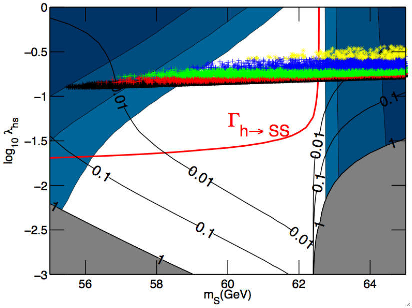
Resulting direct limits:



- Future direct detection experiments (LUX, XENON-1T, DARWIN) will probe most of the parameter space. . .
- . . . yet a small window at $m_S \sim 60$ GeV will remain viable.

Electroweak baryogenesis with S





- Eelectroweak baryongenesis (EWBG) is possible with singlet model, but not at the same time as $\Omega_S/\Omega_{\rm DM} = 1$
- Future DD will squeeze the EWBG parameter space severely.

Summary

- The scalar singlet model is a very simple and appealing DM candidate

Summary

- The scalar singlet model is a very simple and appealing DM candidate
- Signals expected in LHC, direct detection and indirect detection experiments

Summary

- The scalar singlet model is a very simple and appealing DM candidate
- Signals expected in LHC, direct detection and indirect detection experiments
- Constraints on parameter space from DD, ID and LHC are highly complimentary

Summary

- The scalar singlet model is a very simple and appealing DM candidate
- Signals expected in LHC, direct detection and indirect detection experiments
- Constraints on parameter space from DD, ID and LHC are highly complimentary
- Model is excluded as explanation for low-mass DM hints/anomalies

Summary

- The scalar singlet model is a very simple and appealing DM candidate
- Signals expected in LHC, direct detection and indirect detection experiments
- Constraints on parameter space from DD, ID and LHC are highly complimentary
- Model is excluded as explanation for low-mass DM hints/anomalies
- Upcoming experiments (DD especially) will access large parts of the remaining parameter space
