

The puzzle of the evolutionary dynamics of influenza

Luca Peliti

Dipartimento di Scienze Fisiche, Unità CNISM and Sezione INFN
Università “Federico II”, Napoli (Italy)

The virus of influenza

The virus of the flu evolves so fast that it can reinfect the same individual several times even from one year to the next

Basic facts

- ⑥ There are three fundamental groups of flu viruses: A, B et C

Basic facts

- ⑥ There are three fundamental groups of flu viruses: A, B et C
- ⑥ Type A originates global epidemics (pandemics)

Basic facts

- ⑥ There are three fundamental groups of flu viruses: A, B et C
- ⑥ Type A originates global epidemics (pandemics)
- ⑥ Type A is classified in subtypes H_hN_n according to the nature of its HA (Hemoagglutinine) and NA (Neuroaminidase) proteins

Basic facts

- ⑥ There are three fundamental groups of flu viruses: A, B et C
- ⑥ Type A originates global epidemics (pandemics)
- ⑥ Type A is classified in subtypes H_hN_n according to the nature of its HA (Hemoagglutinine) and NA (Neuroaminidase) proteins
- ⑥ Today's dominant subtype is H3N2, but subtype H1N1 (which had disappeared at the beginning of the '60s) is also present (maybe due to a laboratory accident)

The phylogenetic tree for HA

Flu: type A, subtype H3N2, gene HA1

Fitch, Bush, Bender and Cox, 1997

Properties of the tree

- ⑥ The tree exhibits a well-defined backbone: branches have a median lifetime of 1.45 years

Properties of the tree

- ⑥ The tree exhibits a well-defined backbone: branches have a median lifetime of 1.45 years
- ⑥ At any given time, the strain nearest to the backbone can be identified by looking at the number of nonsilent mutations in 18 special codons of the HA gene

Properties of the tree

- ⑥ The tree exhibits a well-defined backbone: branches have a median lifetime of 1.45 years
- ⑥ At any given time, the strain nearest to the backbone can be identified by looking at the number of nonsilent mutations in 18 special codons of the HA gene

Bush, Bender, Subbarao, Cox and Fitch, 1999

Properties of the tree

- ⑥ The tree exhibits a well-defined backbone: branches have a median lifetime of 1.45 years
- ⑥ At any given time, the strain nearest to the backbone can be identified by looking at the number of nonsilent mutations in 18 special codons of the HA gene

Bush, Bender, Subbarao, Cox and Fitch, 1999

- ⑥ The tree does not branch out over long times

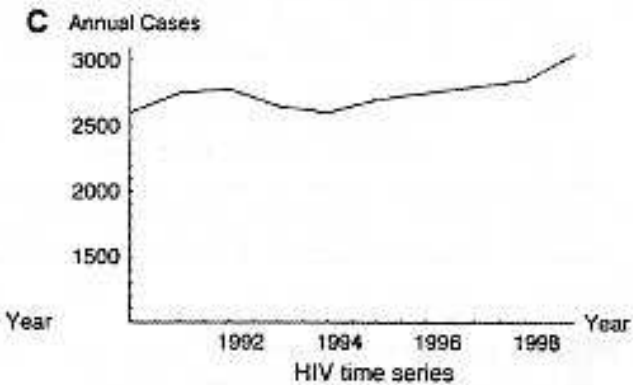

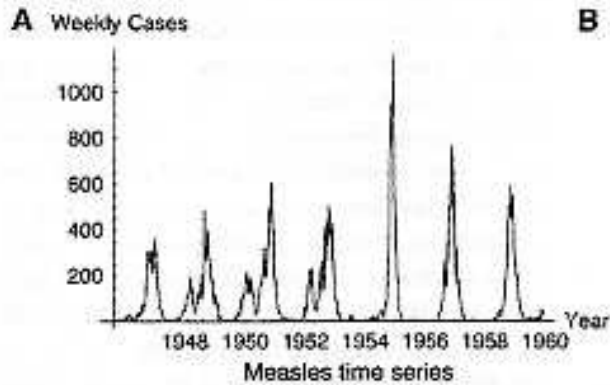

The puzzle

Why does the dominant strain change fast, but the virus does not diversify?

Epidemiology and evolutionary dynamics

Flu vs. in-host HIV evolution

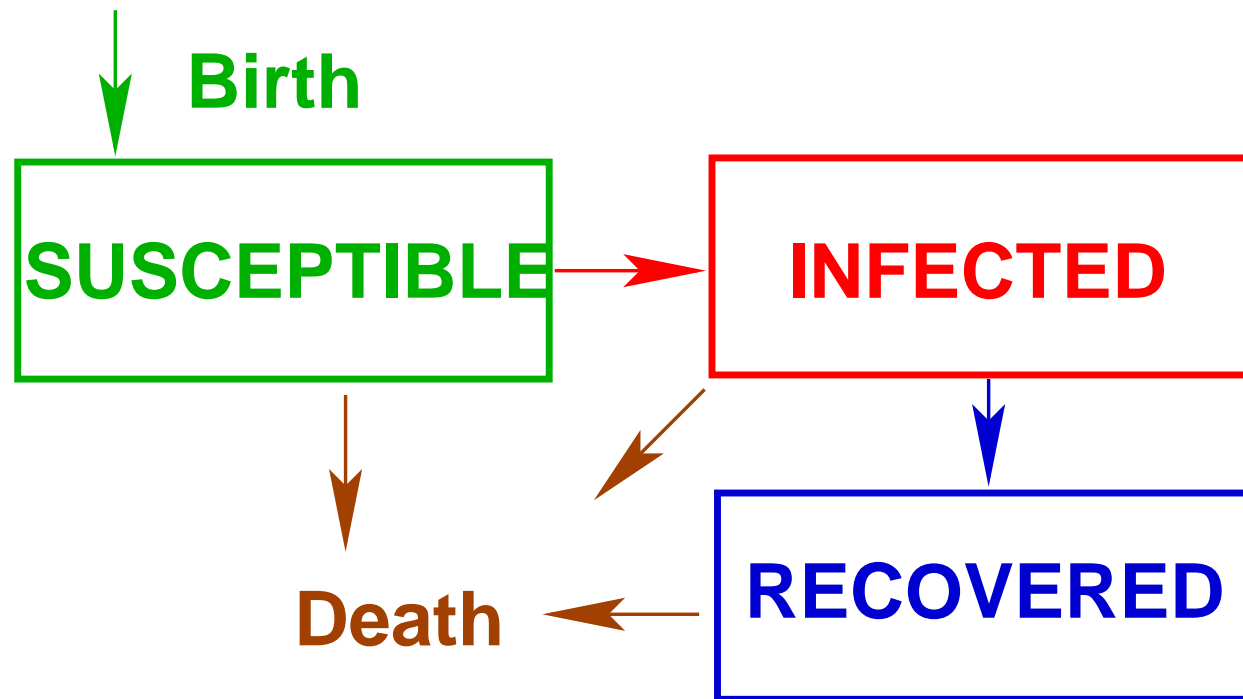

Grenfell et al., 2004

The classic SIR model: Definition

Kermack and McKendrick, 1927

$$\frac{dS}{dt} = N\lambda - \frac{\gamma}{N}SI - \lambda S$$

$$\frac{dI}{dt} = \frac{\gamma}{N}SI - (\rho + \lambda)I$$

The classic SIR model: Behavior

$$S^* = N \frac{\rho + \lambda}{\gamma} \quad I^* = \frac{\lambda}{\rho + \lambda} (N - S^*) \quad \tau \simeq 2\pi \sqrt{\frac{\rho}{\lambda \gamma}} = 2\pi / \sqrt{\beta \lambda \rho}$$
$$\beta = \gamma / \rho$$

Coexisting strains: Modified SIR model

- ⑥ Viral strain defined by k

Coexisting strains: Modified SIR model

- ⑥ Viral strain defined by k
- ⑥ $i_k(t)$: Population infected by strain k at time t

Coexisting strains: Modified SIR model

- ⑥ Viral strain defined by k
- ⑥ $i_k(t)$: Population infected by strain k at time t
- ⑥ $s_k(t)$: Population susceptible to infection by strain k at time t

Coexisting strains: Modified SIR model

- ⑥ Viral strain defined by k
- ⑥ $i_k(t)$: Population infected by strain k at time t
- ⑥ $s_k(t)$: Population susceptible to infection by strain k at time t
- ⑥ **Cross-immunization:** With probability $K_{kk'}$ an individual with antibodies against strain k is also immune against strain k'

One-dimensional strain space: A travelling wave

Andreasen, Lin and Levin, 1997

Mutations generate new strains

Cross-immunity is short-ranged in $|k - k'|$

Akin to spatial propagation of epidemics

Evolution in strain space

Peak oscillations

Gog and Grenfell, 2002; Lin, Andreasen, Casagrandi and Levin, 2003

Long-lasting disease (HIV)?

Comments

- ⑥ The “speed of evolution” dk/dt is compatible with the “natural” values of the parameters ρ (1/one week), λ ($\sim 1/(50 \div 70 \text{ years})$), β (probably $\sim 6 \div 10$) and of the observed substitution rate of the viral strains

Comments

- ⑥ The “speed of evolution” dk/dt is compatible with the “natural” values of the parameters ρ (1/one week), λ ($\sim 1/(50 \div 70 \text{ years})$), β (probably $\sim 6 \div 10$) and of the observed substitution rate of the viral strains
- ⑥ The lack of diversification is *assumed* rather than *derived*

Comments

- ⑥ The “speed of evolution” dk/dt is compatible with the “natural” values of the parameters ρ (1/one week), λ ($\sim 1/(50 \div 70 \text{ years})$), β (probably $\sim 6 \div 10$) and of the observed substitution rate of the viral strains
- ⑥ The lack of diversification is *assumed* rather than *derived*
- ⑥ Need to consider a more general topology of strain space

Many strains

SIR model difficult to generalize:

- ⑥ Cross-immunization with n strains requires at least 2^n states
- ⑥ Need to keep past data indefinitely
- ⑥ Finite population size constraint hard to implement

The bitstring model

Girvan, Callaway, Newman and Strogatz, 2002

- ⑥ Viral strain k identified by a Boolean string $(1, 1, 0, \dots)$
- ⑥ Cross-immunization effectiveness function of the Hamming distance

$$d_H(k, k') = \sum_i (k_i - k'_i)^2$$

- ⑥ Analysis via an individual-based model: Specific (life long) immunity embedded in individual infection history $\Sigma_\alpha = \{k^{(1)}, \dots, k^{(t)}\}$, $\alpha = 1, \dots, N$

Disease incidence

Phase diagram

Comments

- ⑥ Either extinction or boundless proliferation!

Comments

- ⑥ Either extinction or boundless proliferation!
- ⑥ 100% of the population is infected in the steady state!

Comments

- ⑥ Either extinction or boundless proliferation!
- ⑥ 100% of the population is infected in the steady state!
- ⑥ Cross-immunization is not effective!

Comments

- ⑥ Either extinction or boundless proliferation!
- ⑥ 100% of the population is infected in the steady state!
- ⑥ Cross-immunization is not effective!

Branching process:

Comments

- ⑥ Either extinction or boundless proliferation!
- ⑥ 100% of the population is infected in the steady state!
- ⑥ Cross-immunization is not effective!

Branching process:

- ⑥ $\delta \geq r$: Extinction
- ⑥ $\delta < r$: Boundless proliferation

Short term infinite-range immunity

- ⑥ Ferguson, Galvani and Bush (2003) conjecture the existence of a short term (~ 6 months) immunity active against all viral strains, after recovery from an infection

Short term infinite-range immunity

- ⑥ Ferguson, Galvani and Bush (2003) conjecture the existence of a short term (~ 6 months) immunity active against all viral strains, after recovery from an infection
- ⑥ This conjecture is contained in a very complex model, with geographical distribution, many parameters, etc.

Short term infinite-range immunity

- ⑥ Ferguson, Galvani and Bush (2003) conjecture the existence of a short term (~ 6 months) immunity active against all viral strains, after recovery from an infection
- ⑥ This conjecture is contained in a very complex model, with geographical distribution, many parameters, etc.
- ⑥ It has but scanty observational support

Short term infinite-range immunity

- ⑥ Ferguson, Galvani and Bush (2003) conjecture the existence of a short term (~ 6 months) immunity active against all viral strains, after recovery from an infection
- ⑥ This conjecture is contained in a very complex model, with geographical distribution, many parameters, etc.
- ⑥ It has but scanty observational support
- ⑥ Is it sufficient **alone** to describe the observed behavior?

Modified bitstring model

Tria, Lässig, Peliti and Franz, 2004

- ⑥ Individual-based models with bitstring strains
- ⑥ Short-range persistent cross-immunity
- ⑥ Short-term *infinite-range* cross-immunity
- ⑥ Each viral strain k is characterized by its “bare” infectivity β_k , extracted at random

Observables

- ⑥ # individuals infected by strain k : ν_k
- ⑥ Effective number of strains

$$n = \left(\sum_k \nu_k \right)^2 / \left(\sum_k \nu_k^2 \right)$$

- ⑥ Incidence of the disease

$$I = \sum_k \nu_k$$

Effects of short immunity: Incidence and # strains

Random infectivity and no short immunity

Random infectivity *and* short immunity

Incidence and strain number

Random infectivity *and* short immunity

Average infectivity and Hamming distance

With higher time resolution

Phylogenetic tree

Comments

- ⑥ The randomness in the infectivity parameter is difficult to check but not unreasonable
- ⑥ The short-term wide-range immunity has little evidence in its favor
- ⑥ Some properties of the epidemiological dynamics are lacking: e.g., seasonality
- ⑥ The topology of the antigenic space can be more complex

Clusters

Plotkin, Dushoff and Levin, 2002

Clusters identified via genomic distance

Seasonality

Is the strong seasonality of influenza epidemics linked to the limited duration of immunity due to clusters?

Plotkin, Dushoff, Levin and Earn, 2004

Left: Immunity duration 4 yr; Right: Immunity duration 8 yr;
Small sinusoidal perturbations in infectivity

Epochal evolution: Cluster transitions

Koelle, Cobey, Grenfell and Pascual, 2006

Phylogenetic tree of the HA1 gene, color-coded according to the *antigenic* clusters

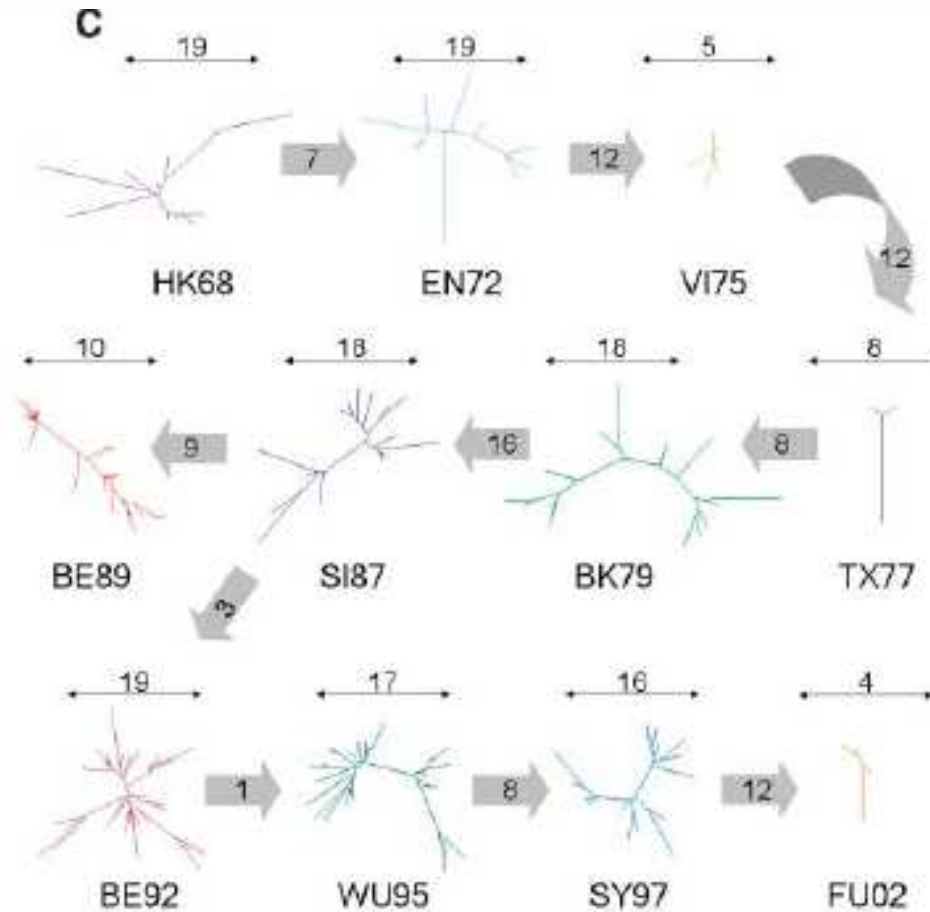

Effects of cluster transitions

Death rate series: Stars denote times after a cluster transition

Clusters trees and their relations

Simulations

Based on a “spin-glass” model of genotype \longrightarrow phenotype mapping

“Influenza escapes immunity along neutral networks”

van Nimwegen, 2006

“Influenza escapes immunity along neutral networks”

van Nimwegen, 2006

Antigenic types

Recker, Pybus, Nee and Gupta, 2007

Explanation

- ⑥ The plot is a projection on the plane of the two principal factors
- ⑥ The path followed in this plane looks more like a zig-zag than a diffusion
- ⑥ Antigenic types seem to reappear over and over again
- ⑥ This happens in spite of an ongoing change at the whole-genome level

Comments

- ⑥ The “antigenic space” has a stranger structure than suspected
- ⑥ The lack of diversification is not *directly* explained by the neutral network model
- ⑥ Antigenic transition is NOT equivalent to shorter host lifetime
- ⑥ These model to not take into account recombination which is *known* to take place during epidemics

Conclusions

- ⑥ In the dynamics of influenza the epidemiological and the evolutionary levels are intertwined

Conclusions

- ⑥ In the dynamics of influenza the epidemiological and the evolutionary levels are intertwined
- ⑥ Answering the puzzle of influenza might also shed light on the behavior of the HIV infection

Conclusions

- ⑥ In the dynamics of influenza the epidemiological and the evolutionary levels are intertwined
- ⑥ Answering the puzzle of influenza might also shed light on the behavior of the HIV infection
- ⑥ But there is still quite some way to go!
