INTRODUCTION

Mainly motivated by the hierarchy problem we consider SUPERSYMMETRY (SUSY) COMPOSITENESS

solves it via top/stopsolves it because whatevercancellations in Higgs massenergy goes into Higgswhatever the energyconstituents' motionBoth generates scalar/Higgs potential dynamically

We consider a Composite 2HDM and the MSSM as minimal realisations of EWSB based on a 2HDM structure

Composite 2HDM (C2HDM) simple natural alternative to the MSSM (SUSY) What do we know about the

MSSM? it provides 2 Higgs doublets and ... we know pretty much everything
C2HDM? it provides 2 Higgs doublets and ... I am going to tell you something (Recall that Nature likes doublets.)

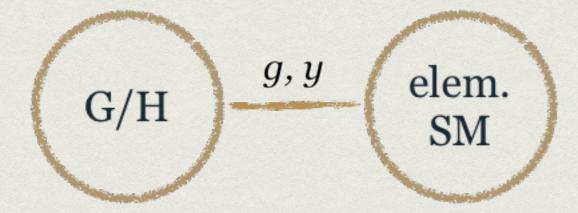

MSSM VS C2HDM

	Supersymmetry (Weak dynamics)	Compositeness (Strong dynamics)
Nature of Higgs	Elementary scalar Φ	Bound state < <u>ψ</u> ψ>~Φ
Quadratic div. Light Higgs	Chiral symmetry m _h ~ m _z (ie, λ ~ g)	No elementary Higgs Pseudo Nambu-Goldstone (pNGBs)
Higgs structure	2HDM (aka MSSM) required for m _{u,d}	2HDM depending on a <u>global symmetry</u>

Q: can you distinguish the two paradigms by looking at 2HDM dynamics?

Compositeness, nothing new?

Two sites structure:

We borrow this idea from QCD: ie,

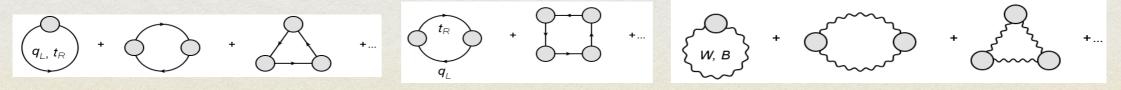

Nature has already realised this mechanism

E

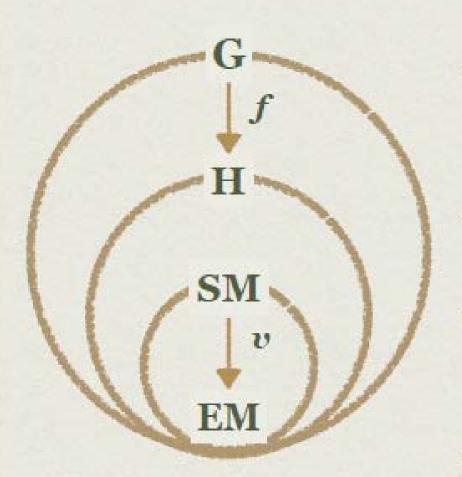

The coset delivers a set of states at a common mass scale:m*

A large separation between new fermions/vector states and Higgses can be achieved if we identify these with pNGBs: m_h

<u>Partial compositeness</u>: composite/elementary mixing (g,y) connect two sites, eventually generating a one-loop effective scalar potential a la Coleman-Weinberg (which we calculated)

Basic rules for a Composite Higgs Model

- a global symmetry G above f (~ TeV) is spontaneously broken down to a subgroup H
- the structure of the Higgs sector is determined by the coset G/H
- H should contain the custodial group
- the number of NGBs (dim G dim H) must be larger than (or at least equal to) 4
- the symmetry G must be explicitly broken to generate the mass for the (otherwise massless) NGBs

In essence:

	Pion Physics	Composite pNGB Higgs	
Fundamental Theory	QCD	QCD-like theory	
Spontaneous sym. breaking	$SU(2)_L \times SU(2)_R \rightarrow SU(2)_V$	$G \rightarrow H$ (spontaneous at compositeness scale f)	
pNGB modes	(п⁰, п±) ~ 135 MeV	h ~ 125 GeV	
Other resonances	ρ ~ 770 MeV, …	New spin 1 and ½ states ~ Multi-TeV	

- Need to choose the correct G->H (spontaneous) breaking to have required NGBs
- Need to break H (explicitly, so pNGBs) via *g* (gauge) and *y* (Yukawa) mixings to generate effective (ie, one-loop) scalar potential for EWSB
- Gauge contribution significant but positive, then look closely at Yukawas (negative)

Model construction

• G/H SO(6)/SO(4) x SO(2)

• the coset delivers 8 NGBs (2 complex Higgs doublets)

• new spin 1/2 and 1 resonances too

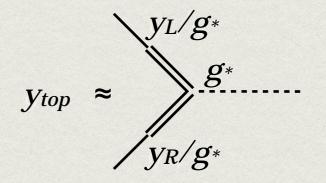

G	Н	N_G	NGBs rep. $[H] = \operatorname{rep.}[\operatorname{SU}(2) \times \operatorname{SU}(2)]$
SO(5)	SO(4)	4	${f 4}=({f 2},{f 2})$
SO(6)	SO(5)	5	${f 5}=({f 1},{f 1})+({f 2},{f 2})$
SO(6)	$SO(4) \times SO(2)$	8	$4_{+2} + \bar{4}_{-2} = 2 \times (2, 2)$
SO(7)	SO(6)	6	$6 = 2 \times (1, 1) + (2, 2)$
SO(7)	G_2	7	7 = (1, 3) + (2, 2)
SO(7)	$SO(5) \times SO(2)$	10	$\mathbf{10_0} = (3, 1) + (1, 3) + (2, 2)$
SO(7)	$[SO(3)]^{3}$	12	$(2, 2, 3) = 3 \times (2, 2)$
$\operatorname{Sp}(6)$	$\operatorname{Sp}(4) \times \operatorname{SU}(2)$	8	$(4, 2) = 2 \times (2, 2), (2, 2) + 2 \times (2, 1)$
SU(5)	$SU(4) \times U(1)$	8	$4_{-5} + \bar{4}_{+5} = 2 \times (2, 2)$
SU(5)	SO(5)	14	${f 14}=({f 3},{f 3})+({f 2},{f 2})+({f 1},{f 1})$

Mrazek et al., 2011

Partial compositeness (y)

Linear interactions between composite and elementary (top) operators

$$\mathcal{L}_{\text{int}} = g J_{\mu} W^{\mu}$$
$$\mathcal{L}_{\text{int}} = y_L q_L \mathcal{O}_L + y_R t_R \mathcal{O}_R$$

, GBs

In our scenario with G/H = SO(6)/SO(4)xSO(2) and fermions in the **6** of SO(6):

All the parameters real \rightarrow CP invariant scenario

- Mixings, masses & Yukawas of heavy tops
- At least 2 heavy (I,J=1,2) top resonances are needed for UV finiteness
- Heavy resonances in the **6** of SO(6) delivers 4 top partners, 1 bottom partner and 1 exotic fermion with Q = 5/3

Custodial symmetry

The predicted leading order correction to the *T* parameter arises from the non-linearity of the GB Lagrangian. In the SO(6)/SO(4)xSO(2) model is

$$\hat{T} \propto 16 \times \frac{v^2}{f^2} \times \frac{\mathrm{Im}[\langle H_1 \rangle^{\dagger} \langle H_2 \rangle]^2}{(|\langle H_1 \rangle|^2 + |\langle H_2 \rangle|^2)^2}$$

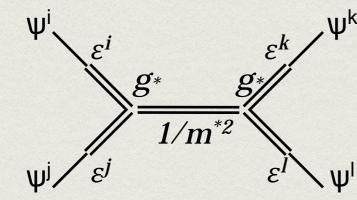

no freedom in the coefficient, fixed by the coset

FCNCs

possible solutions:

- CP (which we assume)
- C₂: H₁ → H₁, H₂ → -H₂ forbidding
 H₂ to acquire a vev (which we don't)

FCNCs mediated by the heavy resonances

$$\sim \epsilon_L^i \epsilon_R^j \epsilon_L^k \epsilon_R^l \left(\frac{g^*}{m^*}\right)^2 a^{ijkl}, \quad a^{ijkl} \sim O(1)$$

for example, for $\Delta S = 2$, $\sim \frac{1}{m^{*2}} \frac{m_d}{v} \frac{m_s}{v}$

• does not require an excessive and unnatural tuning of the parameters

Issues with Higgs-mediated FCNCs

FCNCs can be removed by

- assuming C₂ in the strong sector and in the mixings (ie, Y₁=0): <u>inert C2HDM</u> (not considered here)
- broken C₂ in the strong sector requires (flavour) <u>alignment</u> $Y_1^{IJ} \propto Y_2^{IJ}$ propagating to each type of fermions in the low energy Lagrangian

 $Y_{u}^{ij}Q^{i}u^{j}(a_{1u}H_{1} + a_{2u}H_{2}) + Y_{d}^{ij}Q^{i}d^{j}(a_{1d}H_{1} + a_{2d}H_{2}) + Y_{e}^{ij}L^{i}e^{j}(a_{1e}H_{1} + a_{2e}H_{2}) + h.c.$

(the ratios a_1/a_2 are predicted by the strong dynamics)

The scalar potential

The entire <u>effective</u> potential is fixed by the parameters of the strong sector and the scalar spectrum is entirely predicted by the strong dynamics

Note: here integrate out heavy composite resonances (both fermionic & bosonic) Question is then, what does such compositeness-driven EWSB *predicts*?

The potential up to the fourth order in the Higgs fields:

 $V = m_1^2 H_1^{\dagger} H_1 + m_2^2 H_2^{\dagger} H_2 - \left[m_3^2 H_1^{\dagger} H_2 + \text{h.c.} \right]$ $+ \frac{\lambda_1}{2} (H_1^{\dagger} H_1)^2 + \frac{\lambda_2}{2} (H_2^{\dagger} H_2)^2 + \lambda_3 (H_1^{\dagger} H_1) (H_2^{\dagger} H_2) + \lambda_4 (H_1^{\dagger} H_2) (H_2^{\dagger} H_1)$ $+ \frac{\lambda_5}{2} (H_1^{\dagger} H_2)^2 + \lambda_6 (H_1^{\dagger} H_1) (H_1^{\dagger} H_2) + \lambda_7 (H_2^{\dagger} H_2) (H_1^{\dagger} H_2) + \text{h.c.}$

Light (SM-like) Higgs (ie, no inverted mass hierarchy):

without any tuning, the minimum of the potential is $v \sim f$ $m_{\Pi}^2 \sim \frac{g^{*2}}{16\pi^2} y^2 f^2$ while, in the tuned direction, $*^{2}$

$$m_h^2 \sim \frac{g}{16\pi^2} y^2 v^2$$
 $m_h^2 \sim \frac{N_c}{16\pi^2} g_{\rho}^2 m_t^2$

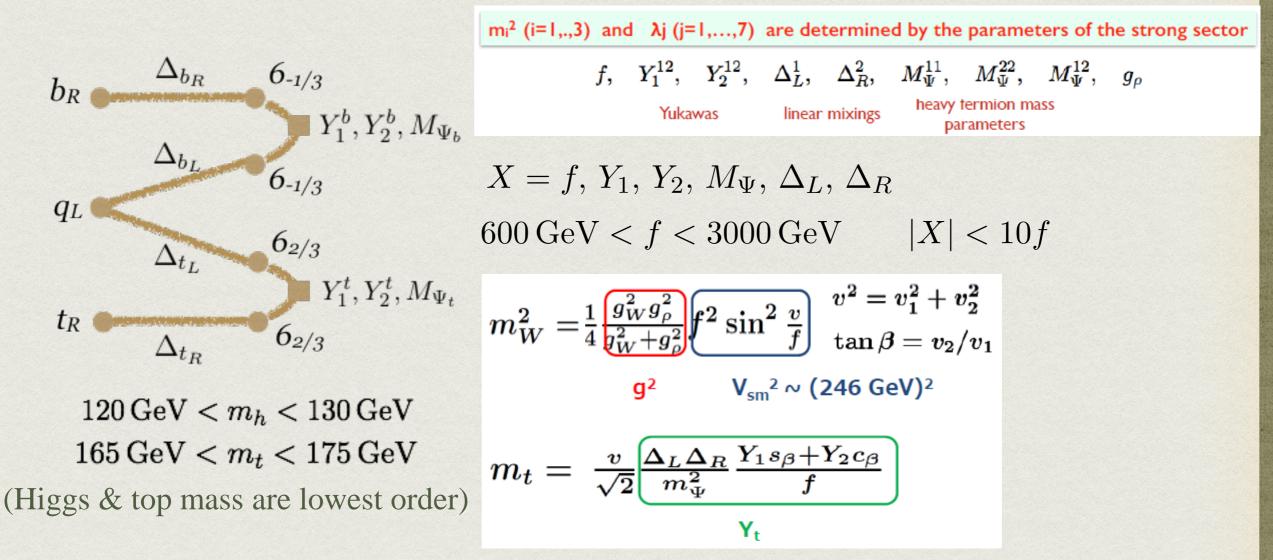

(after reproducing top mass)

Heavy Higgs masses: $M^2 \equiv \frac{m_3^2}{s_\beta c_\beta} \sim \frac{1}{16\pi^2} Y_1 Y_2 \sim \frac{f^2}{16\pi^2}$

Any C2 breaking in the strong sector induces (all $m_3^2 \neq 0, \lambda_6 \neq 0, \lambda_7 \neq 0$ real, following CP conservation in strong sector): $\lambda_6 = \lambda_7 = \frac{5}{3} \frac{m_3^2}{f^2}$ it is not possible to realise a C2HDM scenario with a softly broken Z_2

Sampling the parameter space (now include b)

C2HDM: we adopt the L-R structure based on the 2-site models which represents the minimal choice for a calculable effective potential (*De Curtis et al., 2012*)

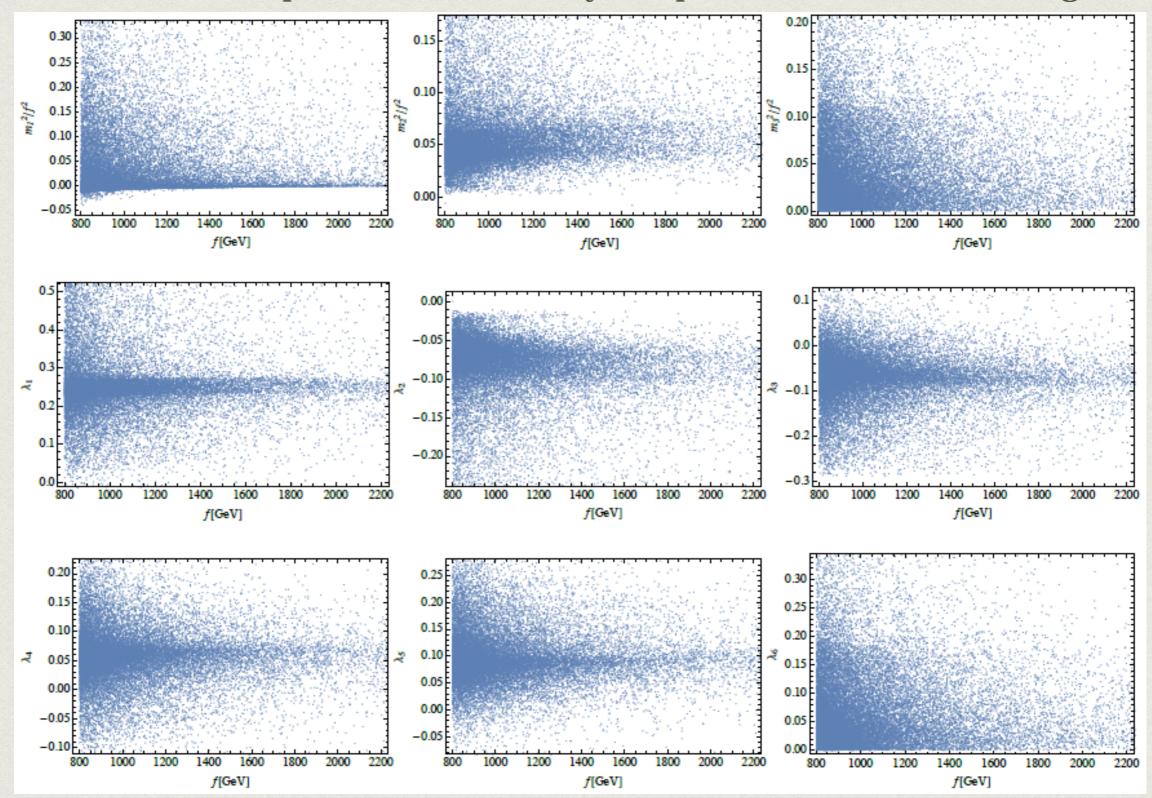

MSSM: we use FeynHiggs 2.14.1 and LHCHXSWG-2015-002 prescriptions:

- 2loop + NNLL resummation
- soft SUSY breaking = Msusy

 $2 < \tan \beta < 45$, $200 \,\text{GeV} < m_A < 1600 \,\text{GeV}$ $1 \,\text{TeV} < M_{\text{SUSY}} < 100 \,\text{TeV}$ $|X_t| < 3M_{\text{SUSY}}$

The entire effective potential is fixed by the parameters of the strong sector

Checked all theoretical constraints (vacuum stability, triviality, unitarity)

Present bounds on the CHM parameters

Yukawa sector $\xi \equiv v_{\rm SM}^2/f^2$

$$\begin{aligned} -\mathcal{L}_{\text{Yukawa}} &= \sum_{f=u,d,l} \frac{m_f}{v_{\text{SM}}} \bar{f} \left[\xi_h^f h + \xi_H^f H - 2i I_f \xi_A^f A \gamma^5 \right] f \\ &+ \frac{\sqrt{2}}{v_{\text{SM}}} \left[V_{ud} \bar{u} \left(-\xi_A^u m_u P_L + \xi_A^d m_d P_R \right) dH^+ + \xi_A^l m_l \bar{\nu} P_R l H^+ \right] + \text{h.c.}, \end{aligned}$$

where $I_f = 1/2(-1/2)$ for f = u(d, l) and the ξ^f coefficients are

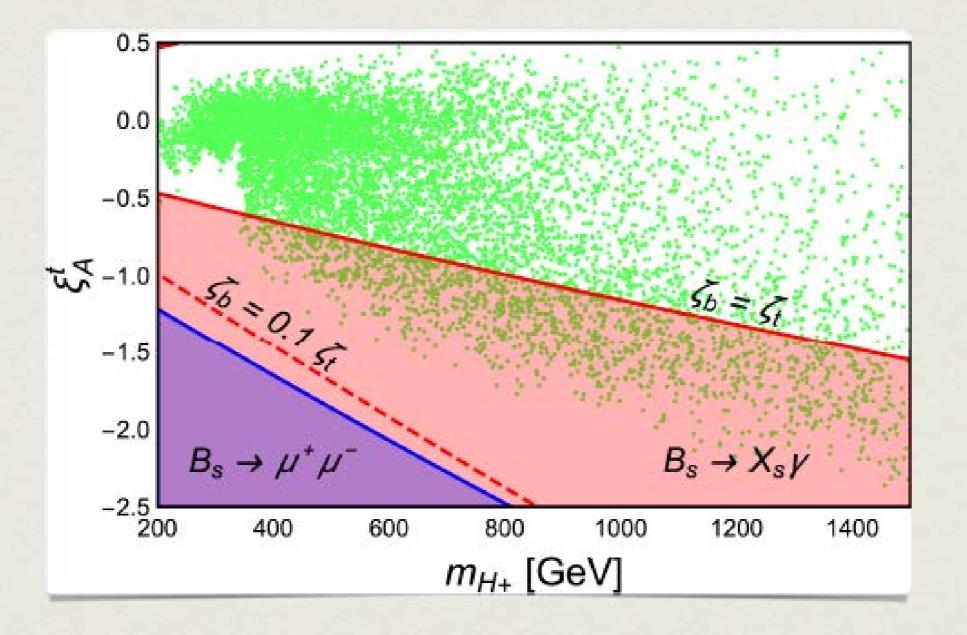

$$\begin{split} \xi_h^f &= (1 + c_f^h \,\xi) \cos\theta + (\zeta_f + c_f^H \,\xi) \sin\theta \,, \quad \xi_H^f = -(1 + c_f^h \,\xi) \sin\theta + (\zeta_f + c_f^H \,\xi) \cos\theta \,, \\ \xi_A^f &= \zeta_f + \xi \left[-\frac{\tan\beta}{2} \frac{1 + \bar{\zeta}_t^2}{(1 + \bar{\zeta}_f \,\tan\beta)^2} , \right] \end{split}$$

with

$$c_f^h = -\frac{1}{2} \frac{3 + \bar{\zeta}_f \tan \beta}{1 + \bar{\zeta}_f \tan \beta}, \quad c_f^H = \frac{1}{2} \frac{\bar{\zeta}_f (1 + \tan^2 \beta)}{(1 + \bar{\zeta}_f \tan \beta)^2},$$
$$\zeta_f = \frac{\bar{\zeta}_f - \tan \beta}{1 + \bar{\zeta}_f \tan \beta}, \quad \bar{\zeta}_f = -\frac{Y_1^f}{Y_2^f}.$$

The parameter θ denotes the mixing between the physical components of the two CP-even states while ζ_f represents the normalised coupling to the fermion f of the CP-even scalar that does not acquire a VEV in the Higgs basis. Since θ is predicted to be small, ζ_f controls the interactions of the Higgs states H, A, H^{\pm} at the zeroth order in ξ .

Flavour constraints

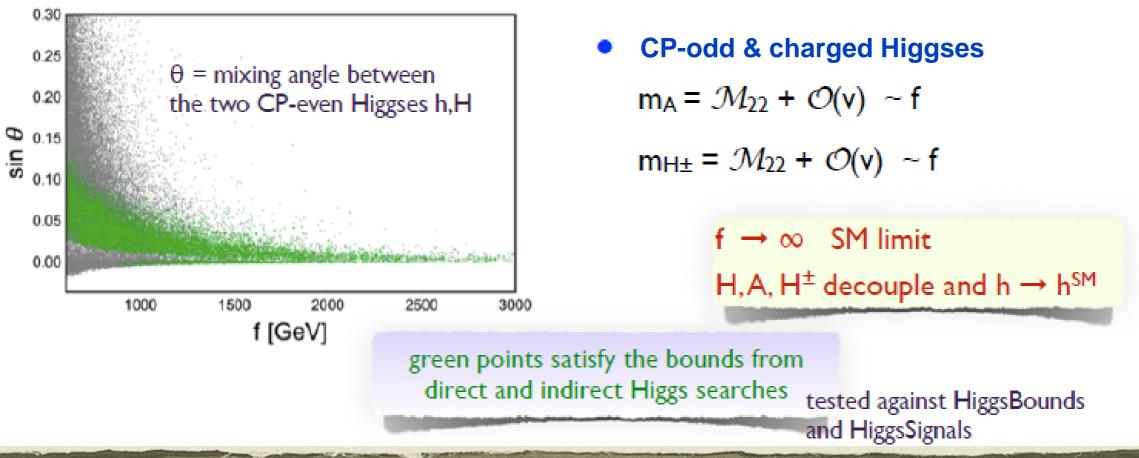

Higgs Boson Masses

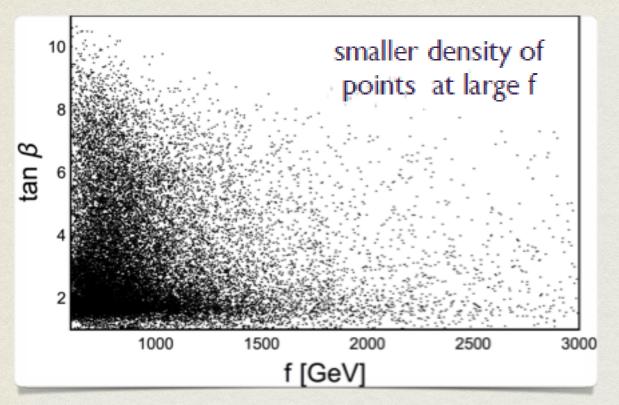

Same physical Higgs states as in the E2HDM: h, H, A, H[±] SM-like Higgs

- They are identified in the Higgs basis after a rotation by an angle β : only one doublet provides a VEV and contains the GBs of W,Z
- CP-even states:

$$\begin{split} m_h^2 &= c_\theta^2 \mathcal{M}_{11}^2 + s_\theta^2 \mathcal{M}_{22}^2 + s_{2\theta} \mathcal{M}_{12}^2 \\ m_H^2 &= s_\theta^2 \mathcal{M}_{11}^2 + c_\theta^2 \mathcal{M}_{22}^2 - s_{2\theta} \mathcal{M}_{12}^2 \end{split} \qquad \tan 2\theta = 2 \frac{\mathcal{M}_{12}^2}{\mathcal{M}_{11}^2 - \mathcal{M}_{22}^2} \end{split}$$

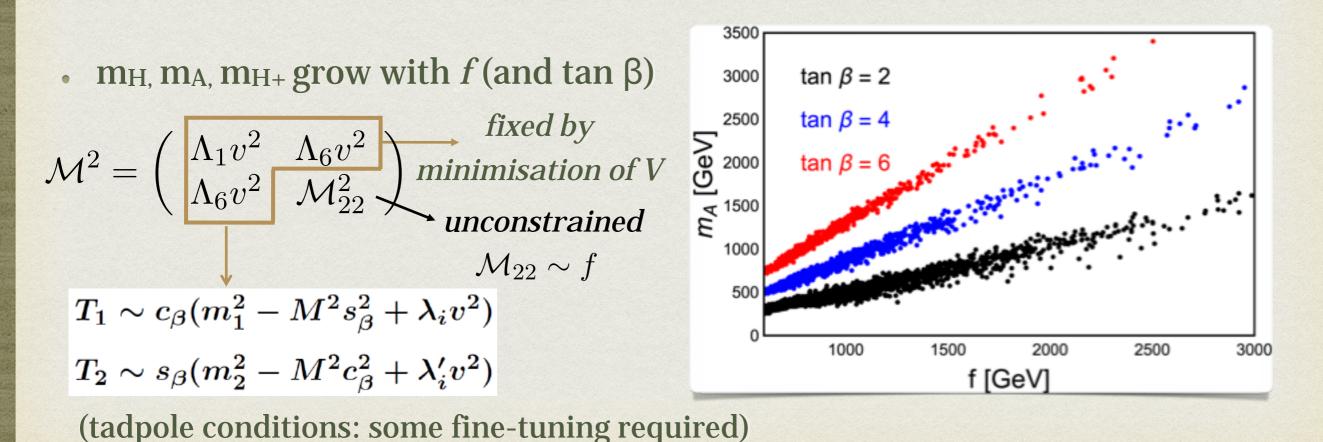

The tadpole conditions involve only \mathcal{M}_{11} and \mathcal{M}_{12} while \mathcal{M}_{22} is ~ unconstrained thus $m_h \sim \mathcal{M}_{11} \sim v \quad m_H \sim \mathcal{M}_{22} \sim f \quad \text{and } \theta \text{ is predicted to be small: } \mathcal{O}(\xi) \text{ for large } f$

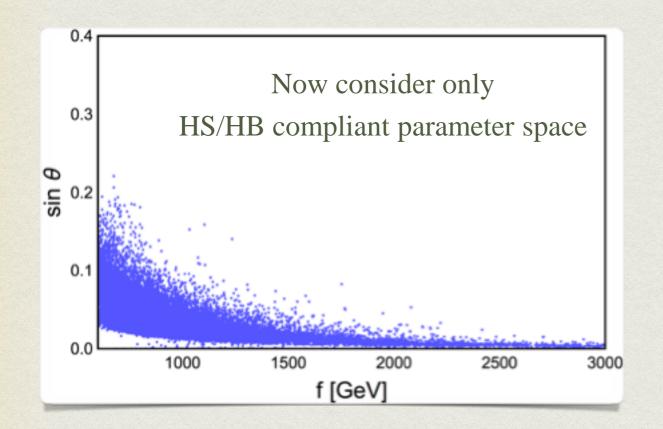

- tan β (usual vev ratio) predicted by the strong sector
- m_h and m_{top} require tan $\beta \sim O(1)$
- larger tuning at large *f*
- values of tan β in the C2HDM and

MSSM cannot be directly compared (next slide)

The SM-like Higgs *h* coupling to *W*,*Z* $\kappa_V = \left(1 - \frac{\xi}{2}\right) \cos \theta, \quad \xi \equiv \frac{v_{\rm SM}^2}{f^2}$

the alignment limit is approached more slowly in the C2HDM than in MSSM

a relevant deviation is present even for no mixing

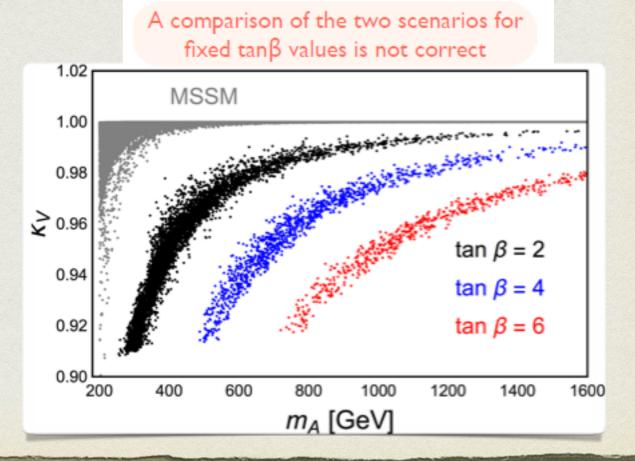

Mixing between the CP-even states *h*, *H*:

$$\tan 2\theta = -2\frac{\Lambda_6 v^2}{\mathcal{M}_{22}^2 - \Lambda_1 v^2} \sim c\frac{v^2}{f^2}$$

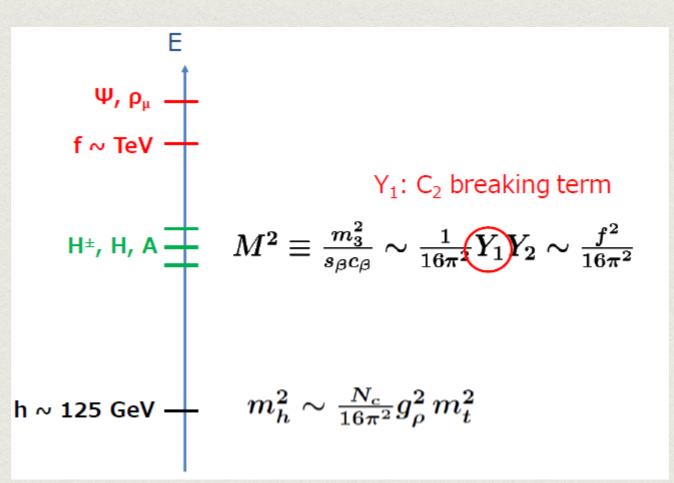

SM-like h requires large f while

very non-SM-like h requires small f

Comment: $\tan\beta$ is basis-dependent. In the E2HDM it is uniquely identified if the Z_2 properties are specified ex. Type-I or Type-II

To recap:

 \star For m_h ~ 125 GeV , we need g_p ~ 5.

★ f $\rightarrow \infty$: All extra Higgses are decoupled → (elementary) SM limit.

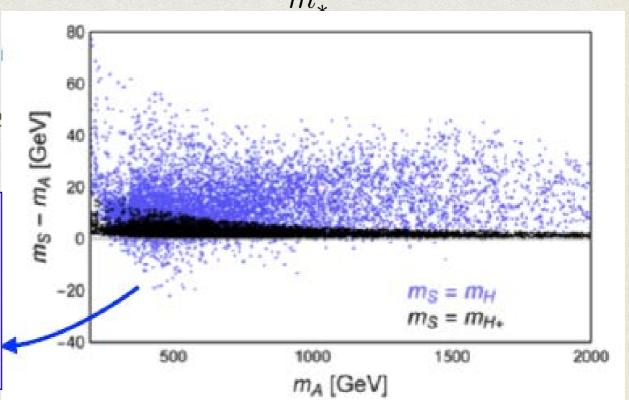

★To get M≠0, we need C₂ breaking (Yukawa alignment is required →A2HDM).

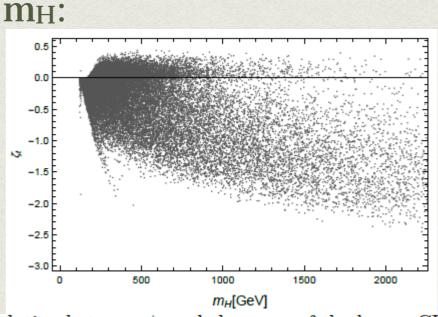

Can heavy Higgs mass spectra reveal C2HDM from MSSM?

- m_{H+} and $m_{A:}$ very close in both scenarios (high degeneracy): very sharp prediction in the C2HDM, $m_{H^{\pm}}^2 - m_A^2 \simeq \frac{\Delta_L^4}{m^4} v^2$
- m_H and m_{A:} larger mass splitting prediction in the C2HDM than in the MSSM (max 15 GeV)
- $H \rightarrow A Z^*$ can be a channel discriminating the two scenarios $A \rightarrow H Z^*$ could also be useful
- $A \rightarrow HZ^*$ could also be useful

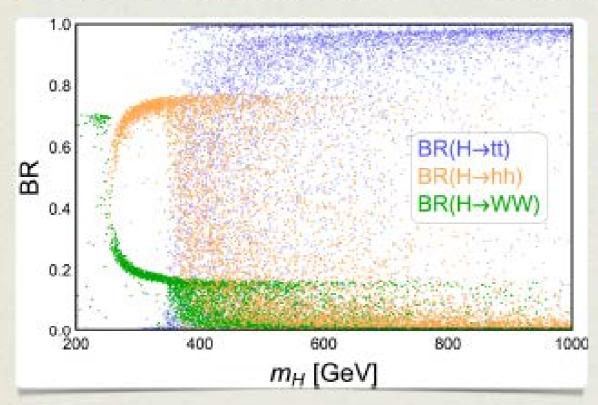

correlation between ζ_t and $\tan\beta$ for all values of f > 700 GeV

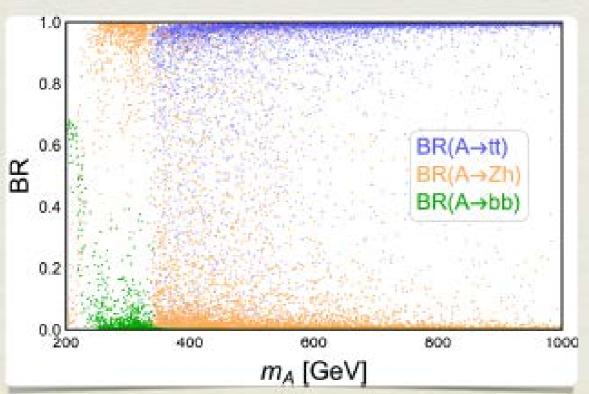

correlation between ζ_t and the mass of the heavy CP-even boson

Heavy Higgs decay modes

 $H \to tt$ represents the main decay mode below the tt threshold, $H \to hh$ dominates $(BR(H \to hh) \sim 80\%, BR(H \to VV) \sim 20\%)$ $\Gamma(H \to t\bar{t}) \approx \frac{3y_t^2}{16\pi} |\zeta_t|^2 m_H$ $\Gamma(H \to hh) \approx \frac{9}{32\pi m_H} (v_{SM}^2 \Lambda_6^2)$ $\Gamma(H \to W^+W^-) \approx 2\Gamma(H \to ZZ) \approx \frac{1}{16\pi m_H} \sin^2 \theta \frac{m_H^4}{v_{SM}^2}$

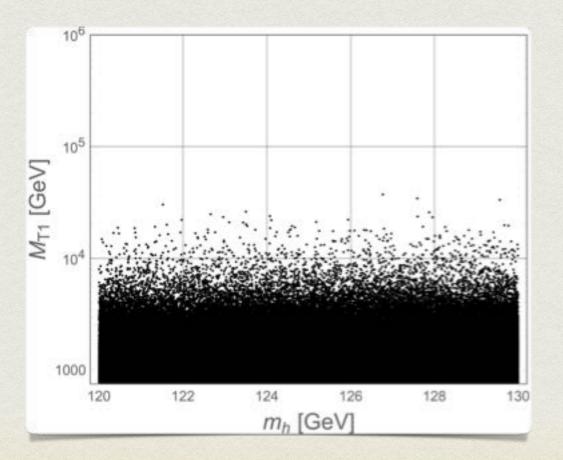

$$BR(A \to t\bar{t}) \approx 1$$

$$BR(A \to b\bar{b}) \approx 8 \times 10^{-4} \left(\frac{\zeta_b^2}{\zeta_t^2}\right)$$

$$BR(A \to \tau^+ \tau^-) \approx 4 \times 10^{-5} \left(\frac{\zeta_\tau^2}{\zeta_t^2}\right)$$

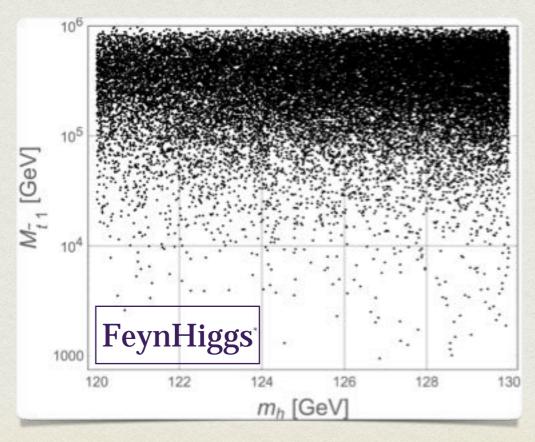

C2HDM: lightest top partner T₁

Reproducing the observed value of m_h requires a fermionic top partner in the C2HDM significantly lighter than the scalar one in the MSSM

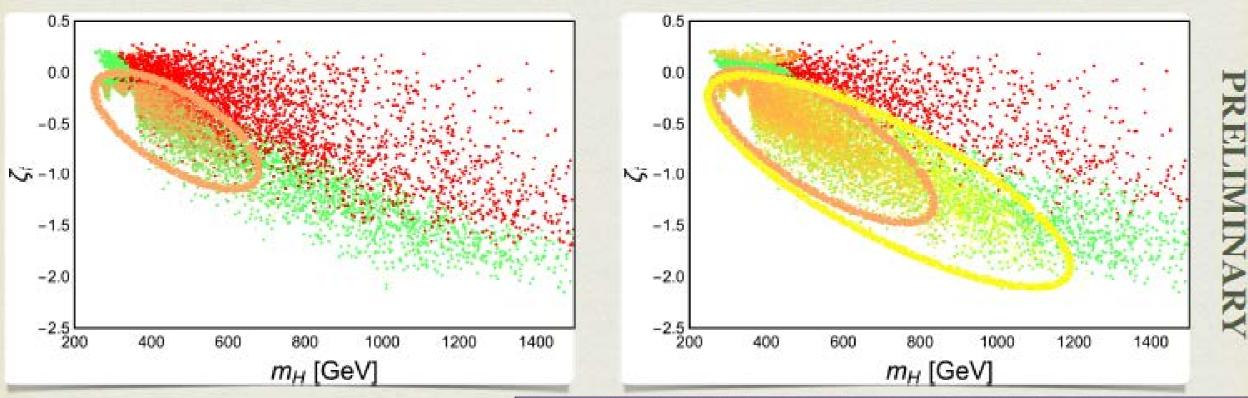

MSSM: lightest stop t₁

interplay between indirect and direct searches $gg \to H \to hh \to bb\gamma\gamma$

end of Run 3

HL-LHC and HE-LHC

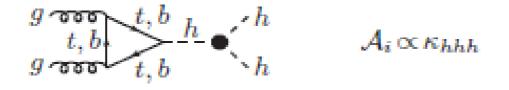

colour legend:

the *Htt* and *Hhh* couplings are strongly correlated and carry the imprint of compositeness

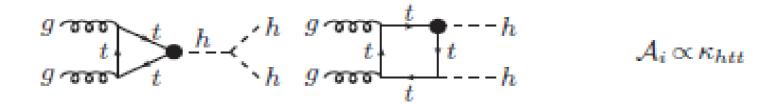

- green: points that pass present constraints at 13 TeV
- red: points that have κ_V , κ_γ and κ_g within 95% CL projected uncertainty at $L = 300 \text{ fb}^{-1}$ (left) and $L = 3000 \text{ fb}^{-1}$ (right) (arXiv:1307.7135)
- orange: points that are 95% CL excluded by direct search at L = 300 fb⁻¹ (left) and L = 3000 fb⁻¹ (right) (CMS PAS HIG-17-008)
 - : points hat are 95% CL excluded by direct search at the HE-LHC (right)

Can di-Higgs at the LHC reveal C2HDM from MSSM?

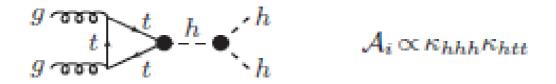

1. modified Higgs trilinear coupling

2. one modified *tth* coupling

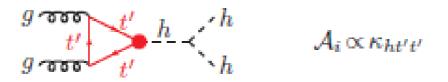

3. modified Higgs trilinear coupling + modified tth coupling

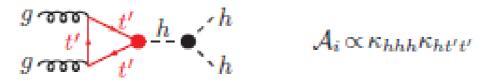

4. two modified *tth* couplings

$$g \underbrace{\tau}_{g} \underbrace{t}_{t} \underbrace{t} \underbrace{t}_{t} \underbrace{t}_{t} \underbrace{t}_{t} \underbrace{t}_{t} \underbrace{t}_{t} \underbrace{t}_{t} \underbrace{t$$

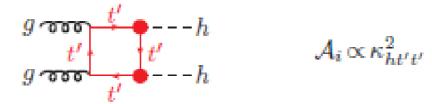

5. VLQ triangle

6. modified Higgs trilinear coupling + VLQ triangle

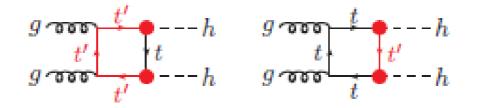

7. VLQ box

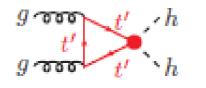

Can we distinguish VLQ vs squark loop effects by looking at di-Higgs mass, pT, etc? (With Jorgen, Luca & Harri.)

Watch this space!

8. VLQ-top box

9. VLQ 4-leg effective vertex

 $A_i \propto \kappa_{hht't'}$

CONCLUSIONS AND PERSPECTIVES

- A C2HDM is the simplest natural 2HDM alternative to its SUSY version (MSSM) in the context of CHMs
- We considered the SO(6)/SO(4)xSO(2) scenario with a broken C₂ which realises a(n Aligned) C2HDM notably different from standard E2HDMs
- Higgs mass spectra *disappointingly similar*, yet existing observables can be used to discriminate between C2HDM and MSSM: *k_V* (delayed decoupling), heavy Higgses' inter-decay patterns, (lightest) top partner spectrum
- Complete phenomenological study of the C2HDM in progress (VLT/VLB decays to additional Higgses, di-Higgs, etc. – SHIFT & HIPPO collaborations)
- Other interesting scenarios: exact C₂, CPV, etc., all making their way into tools
