University

LOFAR: a great survey instrument!

- Wide field of view
- High sensitivity
- ~arcsec resolution

Comparisons

LOFAR Two-metre Sky Survey (LoTSS)

- 150 MHz, 6" resolution, 70 μ Jy/bm

Faint Images of the Radio Sky at 21cm (FIRST)

- 1.4 GHz, 5" resolution, 150 μ Jy/bm

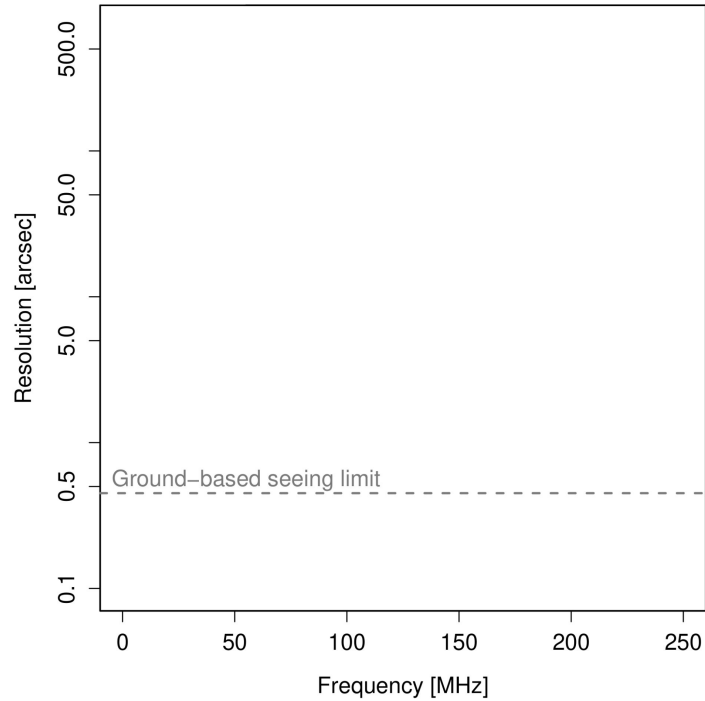

VLA Sky Survey (VLASS)

- 3 GHz, 2.5" resolution, 69 μ Jy/bm (combined)

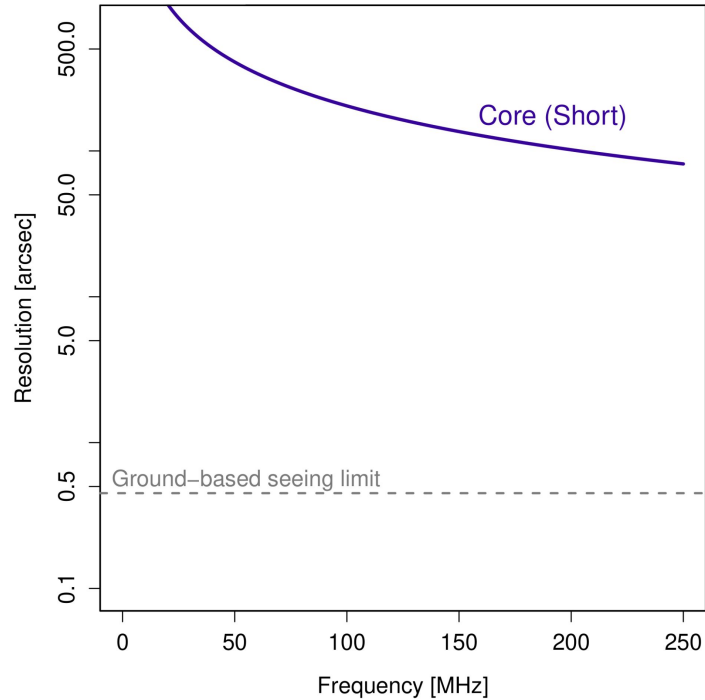

~300 science papers using LoTSS data!

The International LOFAR Telescope (ILT)

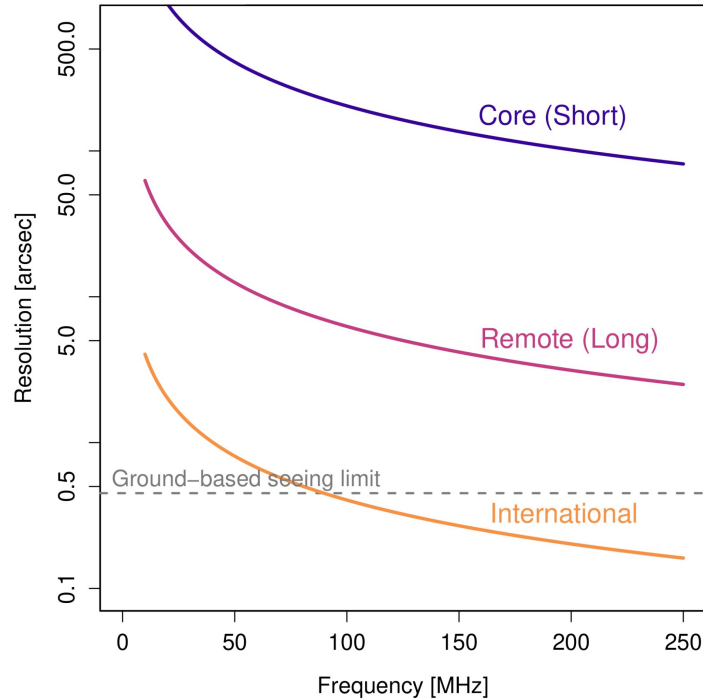

The International LOFAR Telescope (ILT)

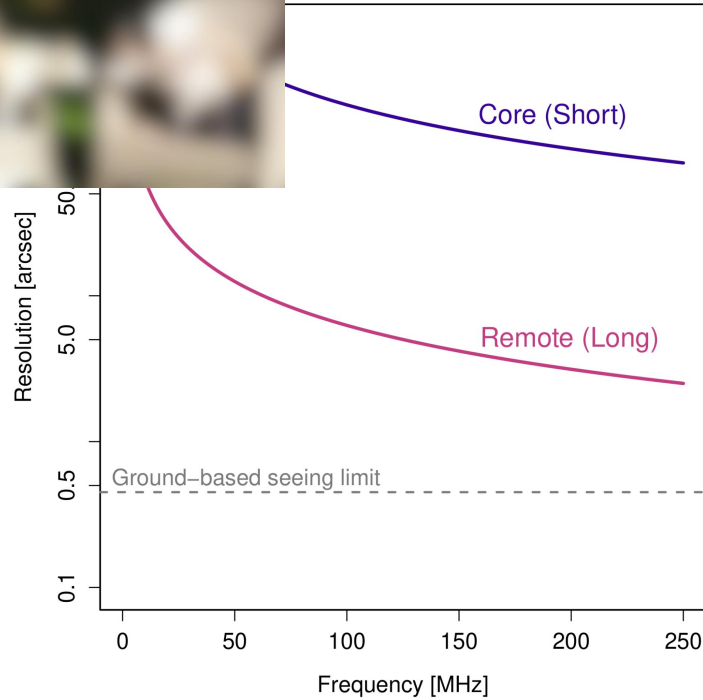

The International LOFAR Telescope (ILT)

What do we get with sub-arcsecond resolution?

Challenges in high resolution at MHz frequencies

- **Ionosphere**: requires directional dependent calibration
- **Data volume**: datasets are 4-20TB per observation
- **Clocks**: remote and international stations on individual clocks
- **Calibrators**: need 'Goldilocks' calibrators for resolution / frequency
- **Source characteristics**: low-frequency absorption, source structure

Challenges in high resolution at MHz frequencies

- Ionosphere: requires directional dependent calibration → **pathfinder for SKA-Low**
- Data volume: datasets are 4-20TB per observation → **SKA-like data volumes now**
- Clocks: remote and international stations on individual clocks
- Calibrators: need 'Goldilocks' calibrators for resolution / frequency
- Source characteristics: low-frequency absorption, source structure

Long Baseline Calibrator Survey (LBCS)

Covers entire Northern sky for HBA (Jackson et al, 2022, 2016)

- Multi-beaming with 3 MHz, 3 min observations of calibrator candidates
- ~30,000 sources in final catalogue, about 1 good calibrator per square degree

- Extending this to LBA (PI: Jackson)

Developing a user-friendly calibration strategy

LoTSS processing

Full array – instrumental effects

Dutch array – phases

de Gasperin et al. 2019

*Calibration uses LOFAR-native tools
but borrowing from VLBI techniques*

LOFAR-VLBI pipeline

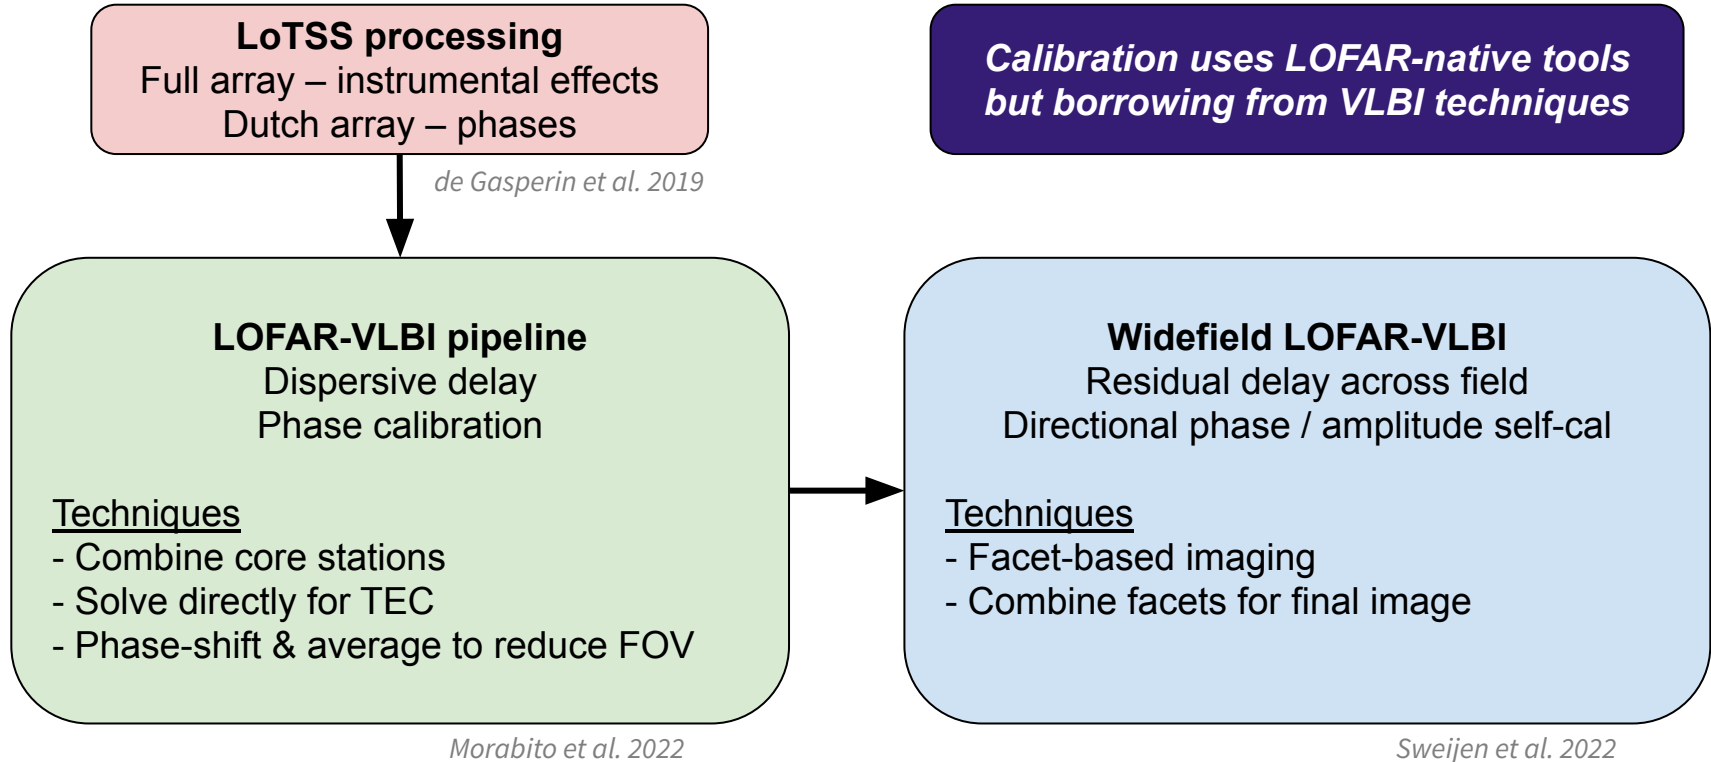

Dispersive delay
Phase calibration

Techniques

- Combine core stations
- Solve directly for TEC
- Phase-shift & average to reduce FOV

Morabito et al. 2022

Developing a user-friendly calibration strategy

Wide-field VLBI with LOFAR

LOFAR-VLBI pipeline

Application: wide area surveys

Field of View limited to radius ~ 1.25 deg (~ 5 deg²)

Widefield LOFAR-VLBI

Application: deep field surveys

Sweijen et al. 2022

Early results

Varenius et al. 2015

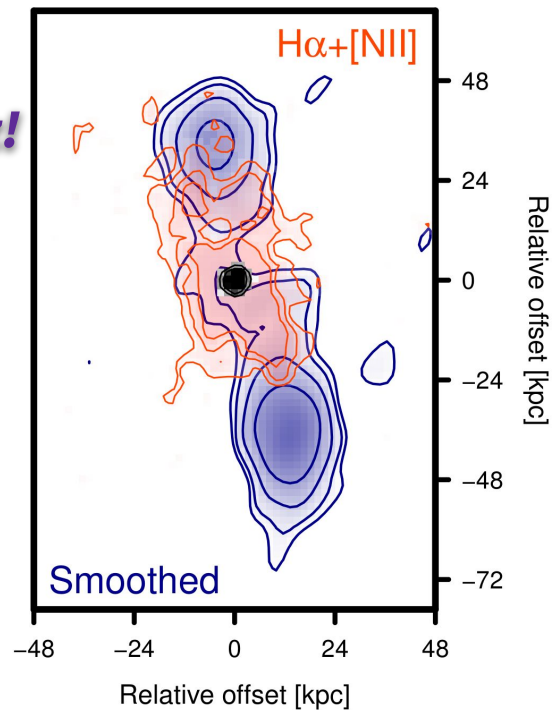

Set the record for high resolution at MHz freqs!

- **Compact objects**: seven new objects, investigated radio spectra of those previously detected at higher frequencies
- **Diffuse emission**: associated with outflow, reduced brightness in region of edge-on star-forming disk

Early results

Morabito et al. 2016

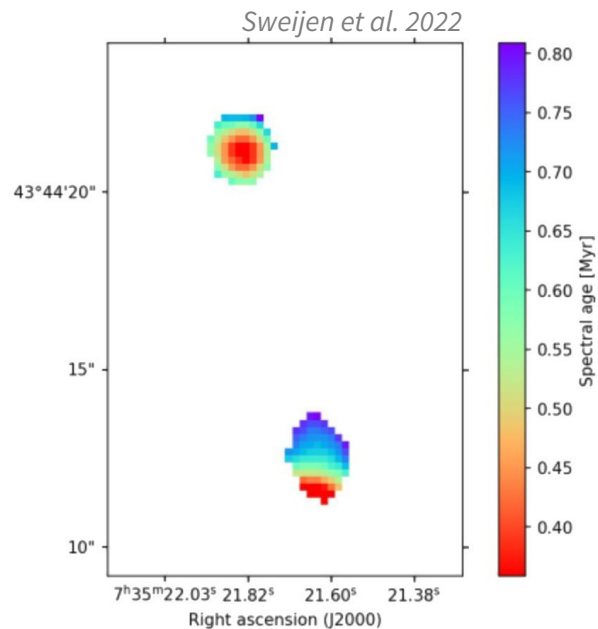

**LBA -
55 MHz!**

Set the record at <100 MHz!

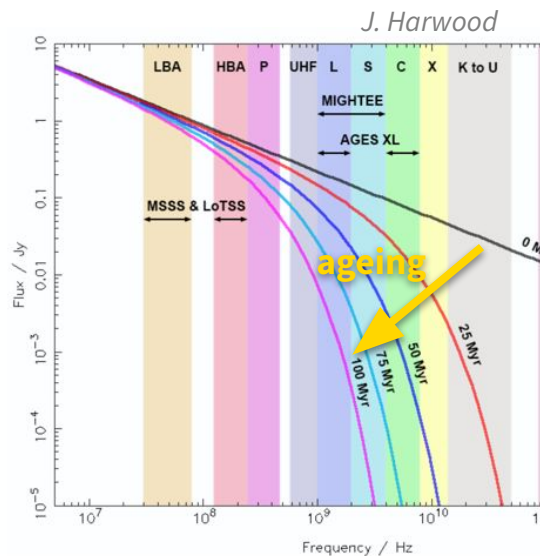

Early results

**LBA -
55 MHz!**

**Later spectral modelling
including HBA**

Set the record at <100 MHz!

Science exploitation

Many science cases, including:

- Jets launched from active galactic nuclei
- Jets interacting with the interstellar medium
- Star formation in nearby galaxies
- Brightness temperature identification of AGN

Special issue of *Astronomy & Astrophysics* with 10 new articles (*published Jan 2022*)

- More than doubling the number of scientific results using LOFAR sub-arcsec resolution!
- Most papers lead by early career researchers

Nature Astronomy article on full-field imaging (*Sweijen et al. 2022*)

Sub-arcsecond imaging with the International LOFAR Telescope

NEW TECHNIQUES DRIVE NEW SCIENCE
Using new data calibration techniques to make high-resolution images, astronomers are uncovering low frequency radio emission on never-before-seen scales. This is a gallery of new science results, revealing the shape of the radio emission in distant galaxies.

INTERNATIONAL LOFAR TELESCOPE
The LOw Frequency ARray (LOFAR) is a radio telescope with antennas spread across 8 European countries. It operates at frequencies around the FM radio band, where jets from black holes are particularly bright.

LOFAR Two-metre Sky Survey + High Resolution

Post-processing LoTSS at high resolution will yield *the first sub-arcsecond Northern sky radio survey*

	LoTSS	LoTSS-HR	VLASS
resolution	6"	0.3"	2.5"
Area [deg ²]	20,000	20,000	33,885
noise	70 μ Jy/bm	\sim 50 μ Jy/bm	69 μ Jy/bm
Sources per deg ²	780	\sim 50 (> 10 mJy)	\sim 148

Main takeaways

- The International LOFAR Telescope (ILT) provides otherwise inaccessible spatially resolved information at low frequencies - particularly powerful when combined with higher frequency observations at similar resolutions
- Sweden has a strong track record with LOFAR-VLBI, focused on detailed studies of star-forming and starburst galaxies
- LOFAR-VLBI is becoming more accessible thanks to our Long Baseline Working Group, which is driven by active early career researchers

Developing a calibration strategy

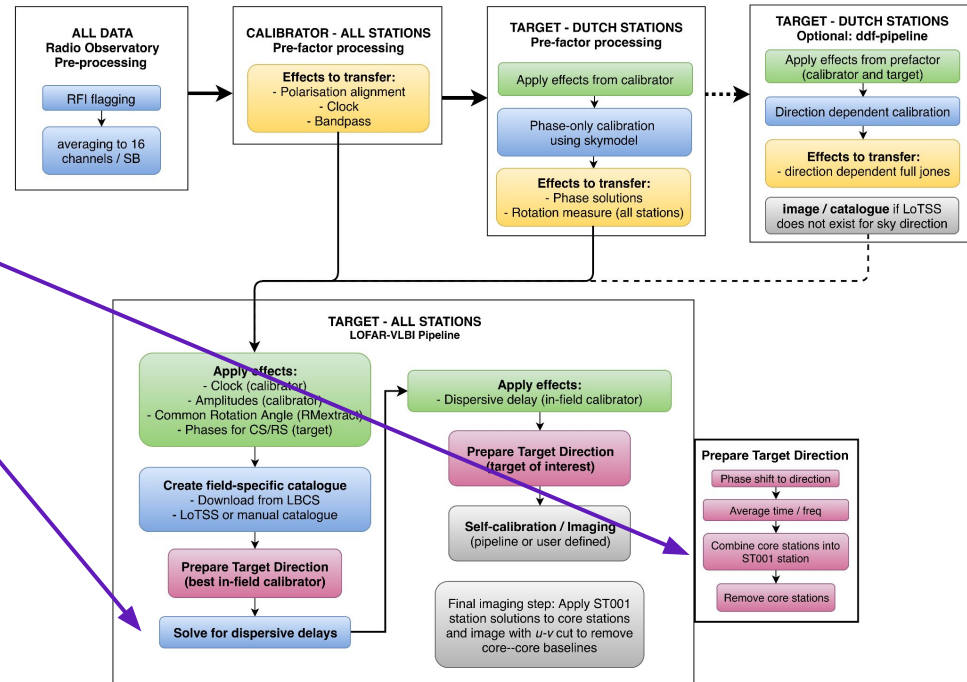

Use LOFAR-native tools to:

- Correct clock offsets ($\tau = 100 - 200$ ns)
- Combine core stations into a ‘super-station’ to help anchor calibration / reduce data volume
- Solve for dispersive delay ($\tau \sim 200 - 300$ ns)

Publicly available on github (*Morabito et al. 2022*)

Built as an extension to the processing for the LOFAR Two-metre Sky Survey (*Shimwell et al. 2017,2019,2022*)

Basis for imaging full field of view (*Sweijen et al. 2022*)

Developing a calibration strategy

Calibration at high resolution has to handle lower signal to noise on long baselines

To cope with this a technique called **fringe-fitting** was developed to increase the solution intervals by solving for *delays* and *rates* in addition to a phase offset:

$$\Delta\phi_{\nu,t} = \phi_0 + \left(\frac{\delta\phi}{\delta\nu} \Delta\nu + \frac{\delta\phi}{\delta t} \Delta t \right)$$

Developing a calibration strategy

Fringe-fitting algorithms have, until very recently, only been able to cope with *non-dispersive delays* (i.e., phase is linear with frequency)

LOFAR is dominated by *dispersive delays* due to the ionosphere

Astrometry and flux density scale

Compare original LoTSS image with 6" image from
Dutch dataset

- LoTSS has 20 mas offset from PanSTARRS →
compared to LoTSS is 28 mas
- Flux density – scatter around one-to-one line
sources in LoTSS to 6" image

Brightness temperature at 150 MHz

- Identified 795 (790) high brightness temperature sources in Lockman Hole
 - 83% are otherwise identified as AGN (91% when using only peak intensity)
 - **66 new AGN identifications!**
- Comparison to SED fitting shows:
 - 22% of detected radio-quiet AGN and 12% of star-forming galaxies have high brightness temperatures
 - ***implies mixture of different radio emission mechanisms in populations***
- Detected vs. detectable sources split below 2 mJy
 - Consistent with mixed populations of sources at low flux densities

Using brightness temperature measurements with sub-arcsecond ILT observations is a reliable way to select AGN, in particular when ancillary data is inadequate

How much of the radio emission is due to AGN?

For unresolved, non-radio excess sources, we make the simple assumption that:

- L_{AGN} = peak intensity, high resolution map
- L_{SFR} = (total flux density, 6" resolution map) - L_{AGN}

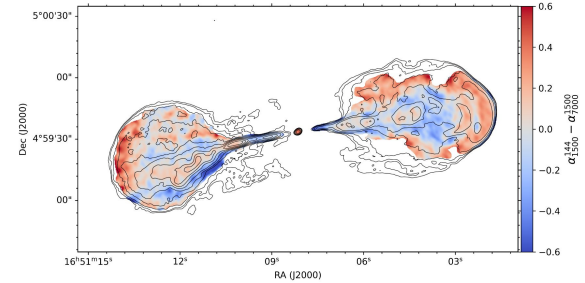

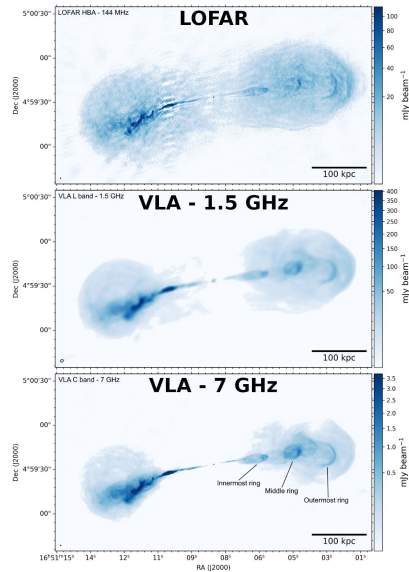

$L_{\text{AGN}}/L_{\text{SFR}}$	
Class	Median
RQAGN	0.89 ± 0.69
SFG	0.79 ± 0.42
Unclass	1.07 ± 0.64
Total	0.90 ± 0.55

$L_{\text{AGN}}/L_{\text{total}}$	
Class	Median
RQAGN	0.47 ± 0.21
SFG	0.44 ± 0.14
Unclass	0.49 ± 0.16
Total	0.47 ± 0.17

Jets from active galactic nuclei

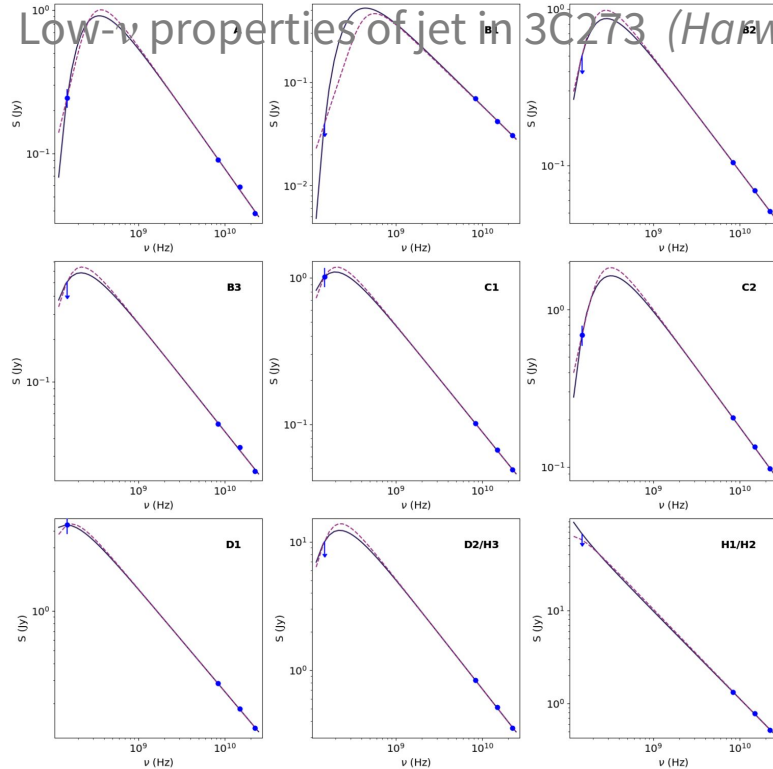

(Timmerman et al., 2022)

Spectral information - aided by LOFAR - shows rings are consistent with the active galactic nuclei intermittently turning 'on' and 'off'

The jet in 3C273

Low- ν properties of jet in 3C273 (Harwood, Mooney et al., 2022)

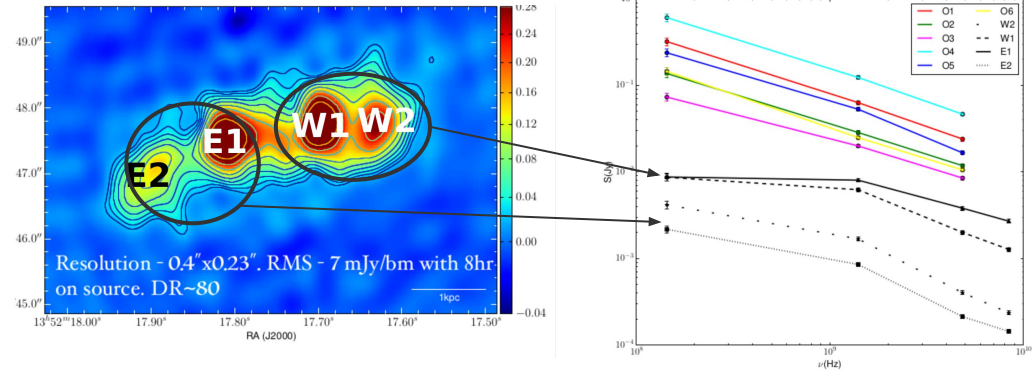

Jet power consistent with high frequencies
Low- ν high resolution enabled spectral modelling of individual components!

Jets interacting with the interstellar medium

most galaxy (Kukreti et al., 2022)

Low-frequency spectra in young jet components show evidence for interaction with interstellar medium

Star formation in nearby galaxies

Ramírez-Olivencia et al. 2022)

LOFAR images reveal diffuse emission in outflow powered by a starburst, possibly triggered by merger with galaxy hosting an active galactic nucleus

Extending to < 100 MHz with the LBA

below 100 MHz! They allow us to

Enabling science: the cutting edge

Imaging of complete 5 deg² field of view for Lockman Hole (*Sweijen et al. 2022*)

https://home.strw.leidenuniv.nl/~sweijen/lockman_aladin.php

LOFAR wide-field high resolution imaging on Lockman Hole

Fun fact: This high resolution image contains about 7 billion pixels, almost as much as the FIRST survey!

Left: A typical direction dependent calibrated ddf-pipeline image of the Dutch array at 6', using roughly 46 MHz of bandwidth. The RMS level is ~75 uJy/beam.

Right: A 0.11"/px direction dependent calibrated image at 0.4"x0.3", using 46 MHz of bandwidth, made with WSClean+IDG using both TEC and gain screens. Initial and self-calibration was done on an LBCS source upper left, just outside the first circle, followed by secondary self-calibration on 41 sources that had peak flux density >25 mJy/beam on the 1" map. The RMS noise level is currently ~30 uJy/beam near the center.

Usage: The high-resolution view is locked to the low-resolution view. Pan around on the left image, and the high-resolution map will follow (the other way around does not work).

The cyan circles indicate 1 deg and 2 deg diameter, respectively. The red circle indicates a 2.5 deg diameter.

The main challenge at low frequencies

Before ionospheric correction

After ionospheric correction
