UNIVERSITY OF COPENHAGEN

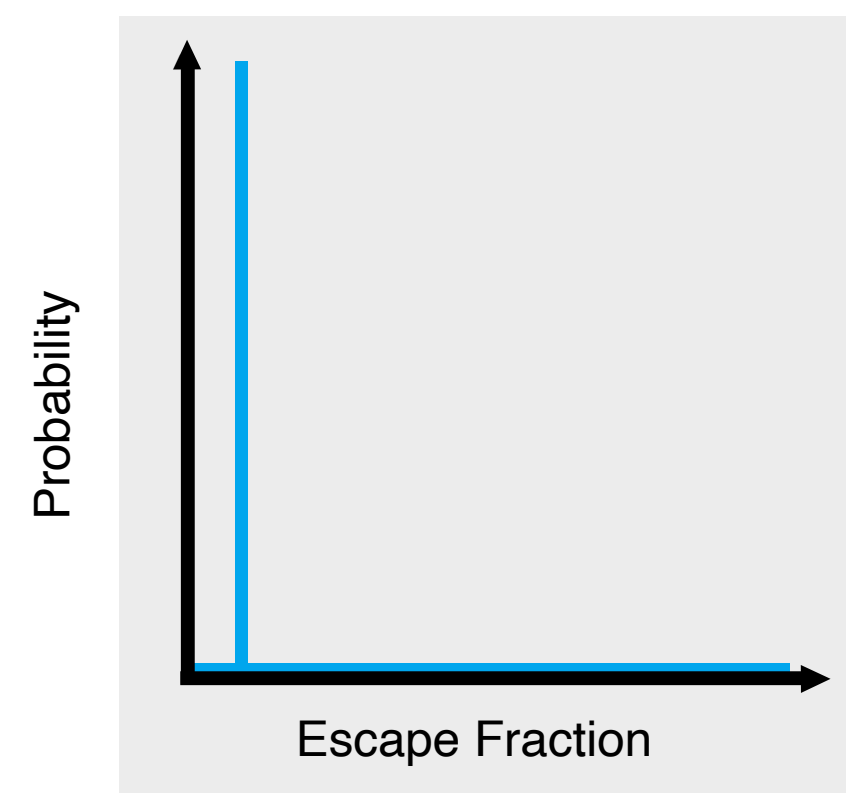

The reionisation history

- Number of sources producing ionising photons
- Ionising photon production efficiency
- **The ionising photon escape fraction distribution**

How does the distribution connect to the physical picture?

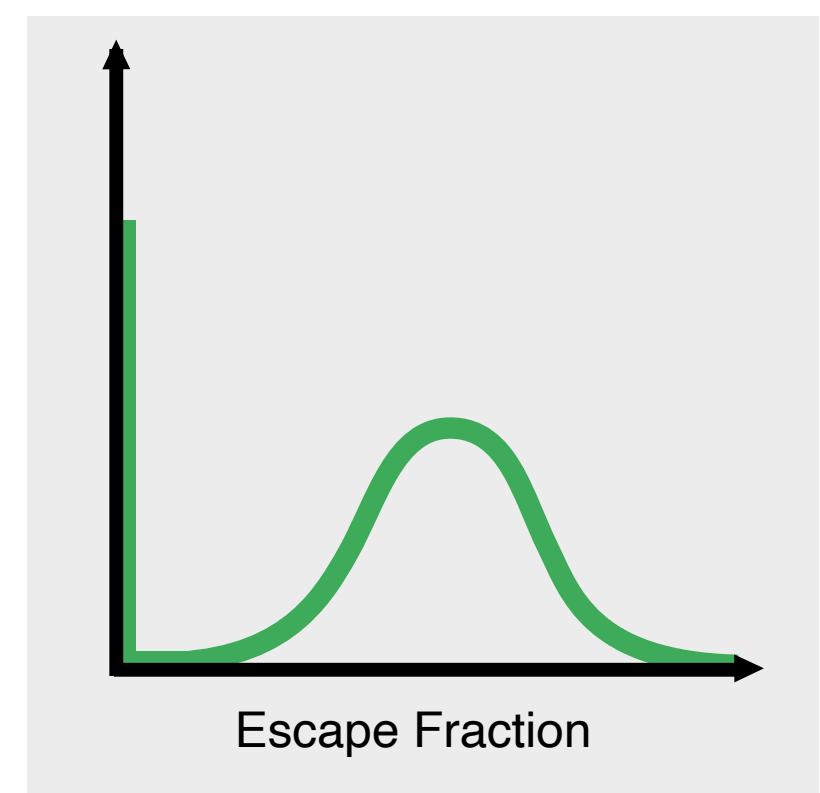

Constant Model

Log-Normal Model

Exponential Model

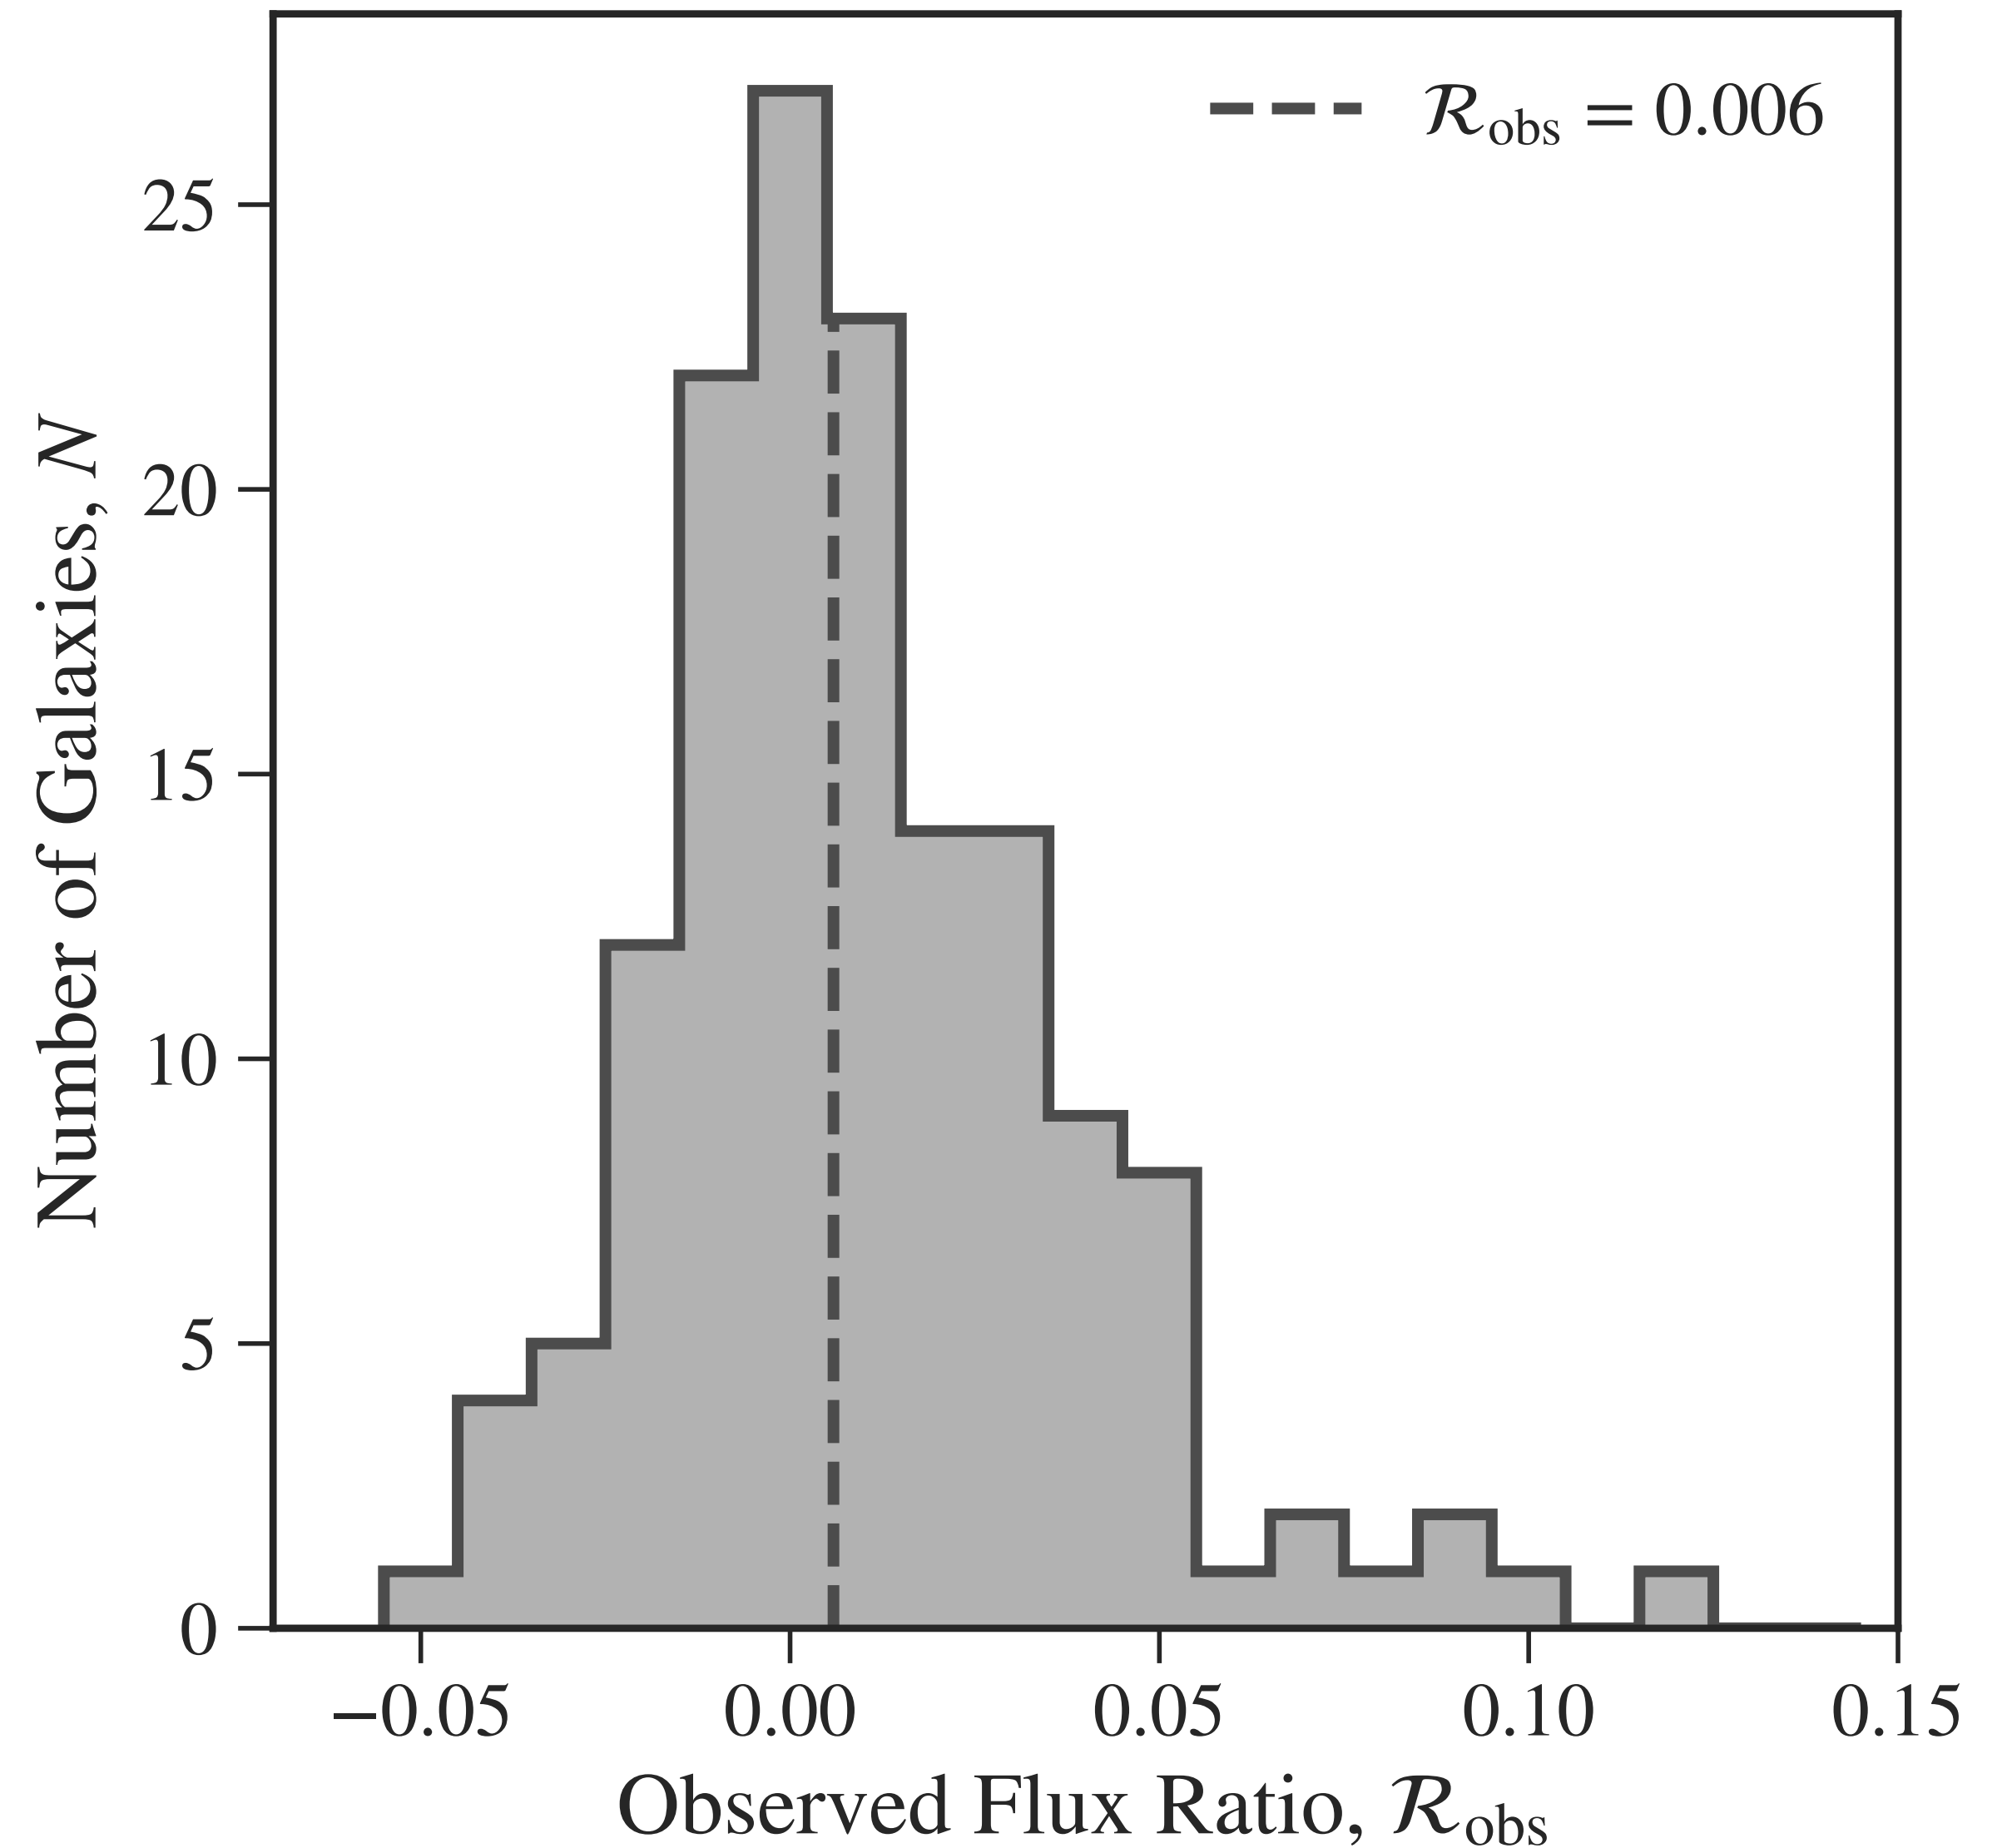

Bimodal Model

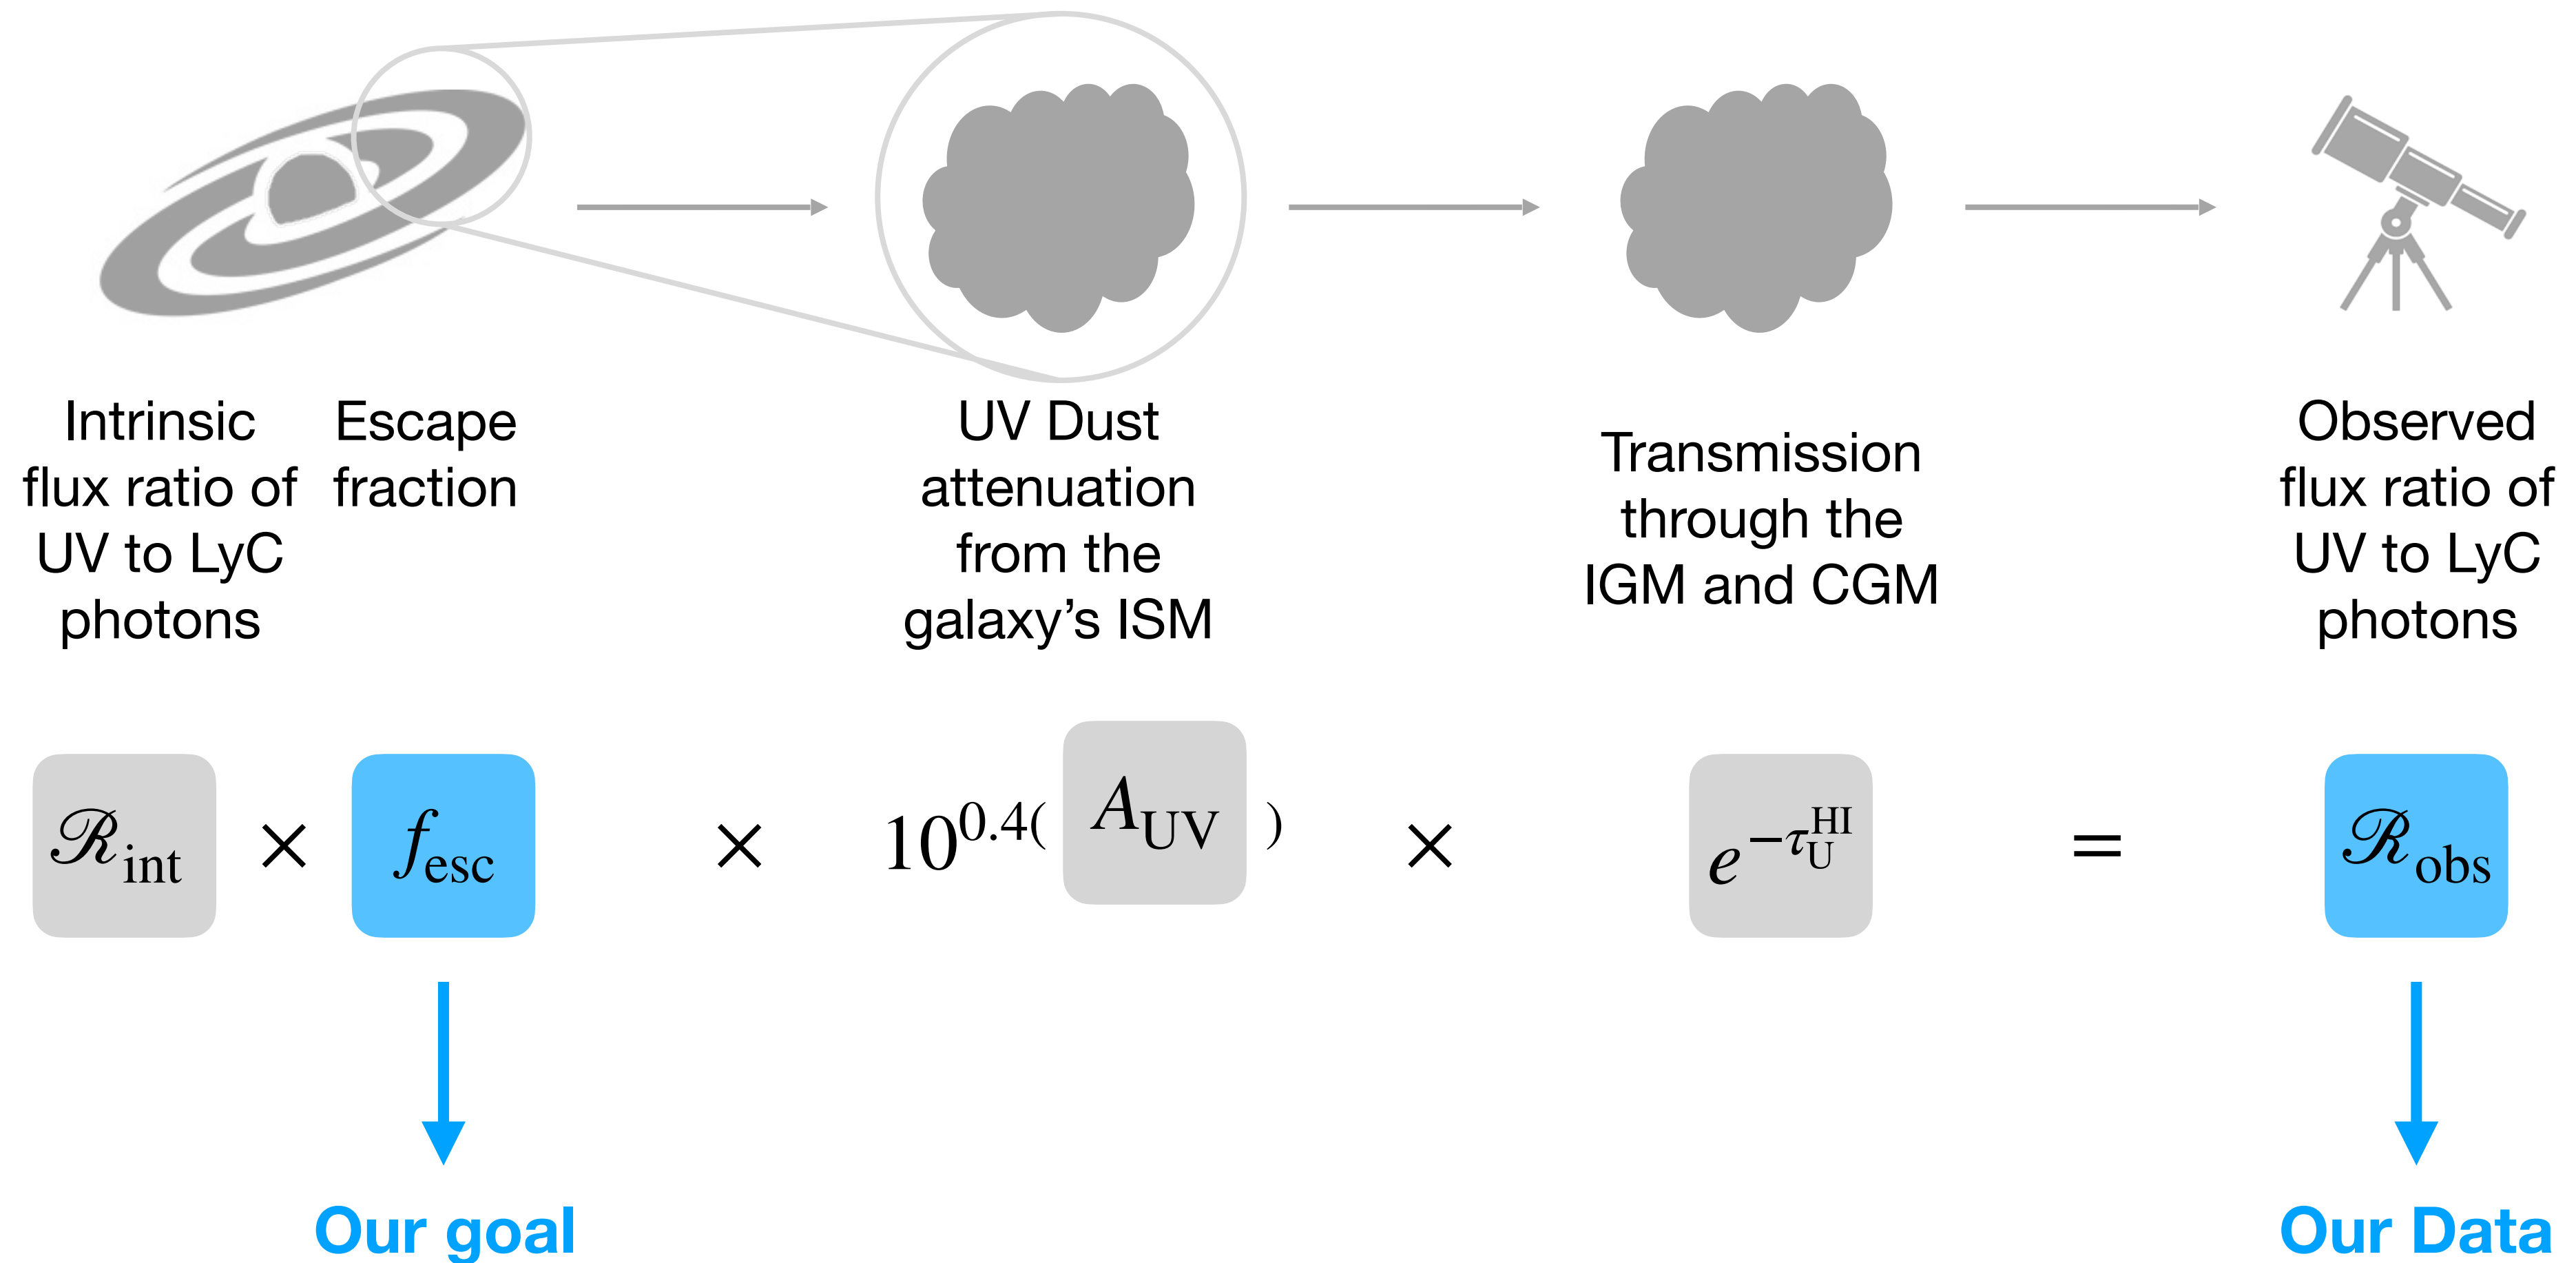

The Data

- Selection of **148 star-forming** galaxies from VANDELS survey
 - **Spectroscopic redshift:**
 $3.35 < z < 3.95$
 - **LyC photometry**
(VIMOS U-band)
 - **Non-ionising UV photometry.**
(HST F606W)

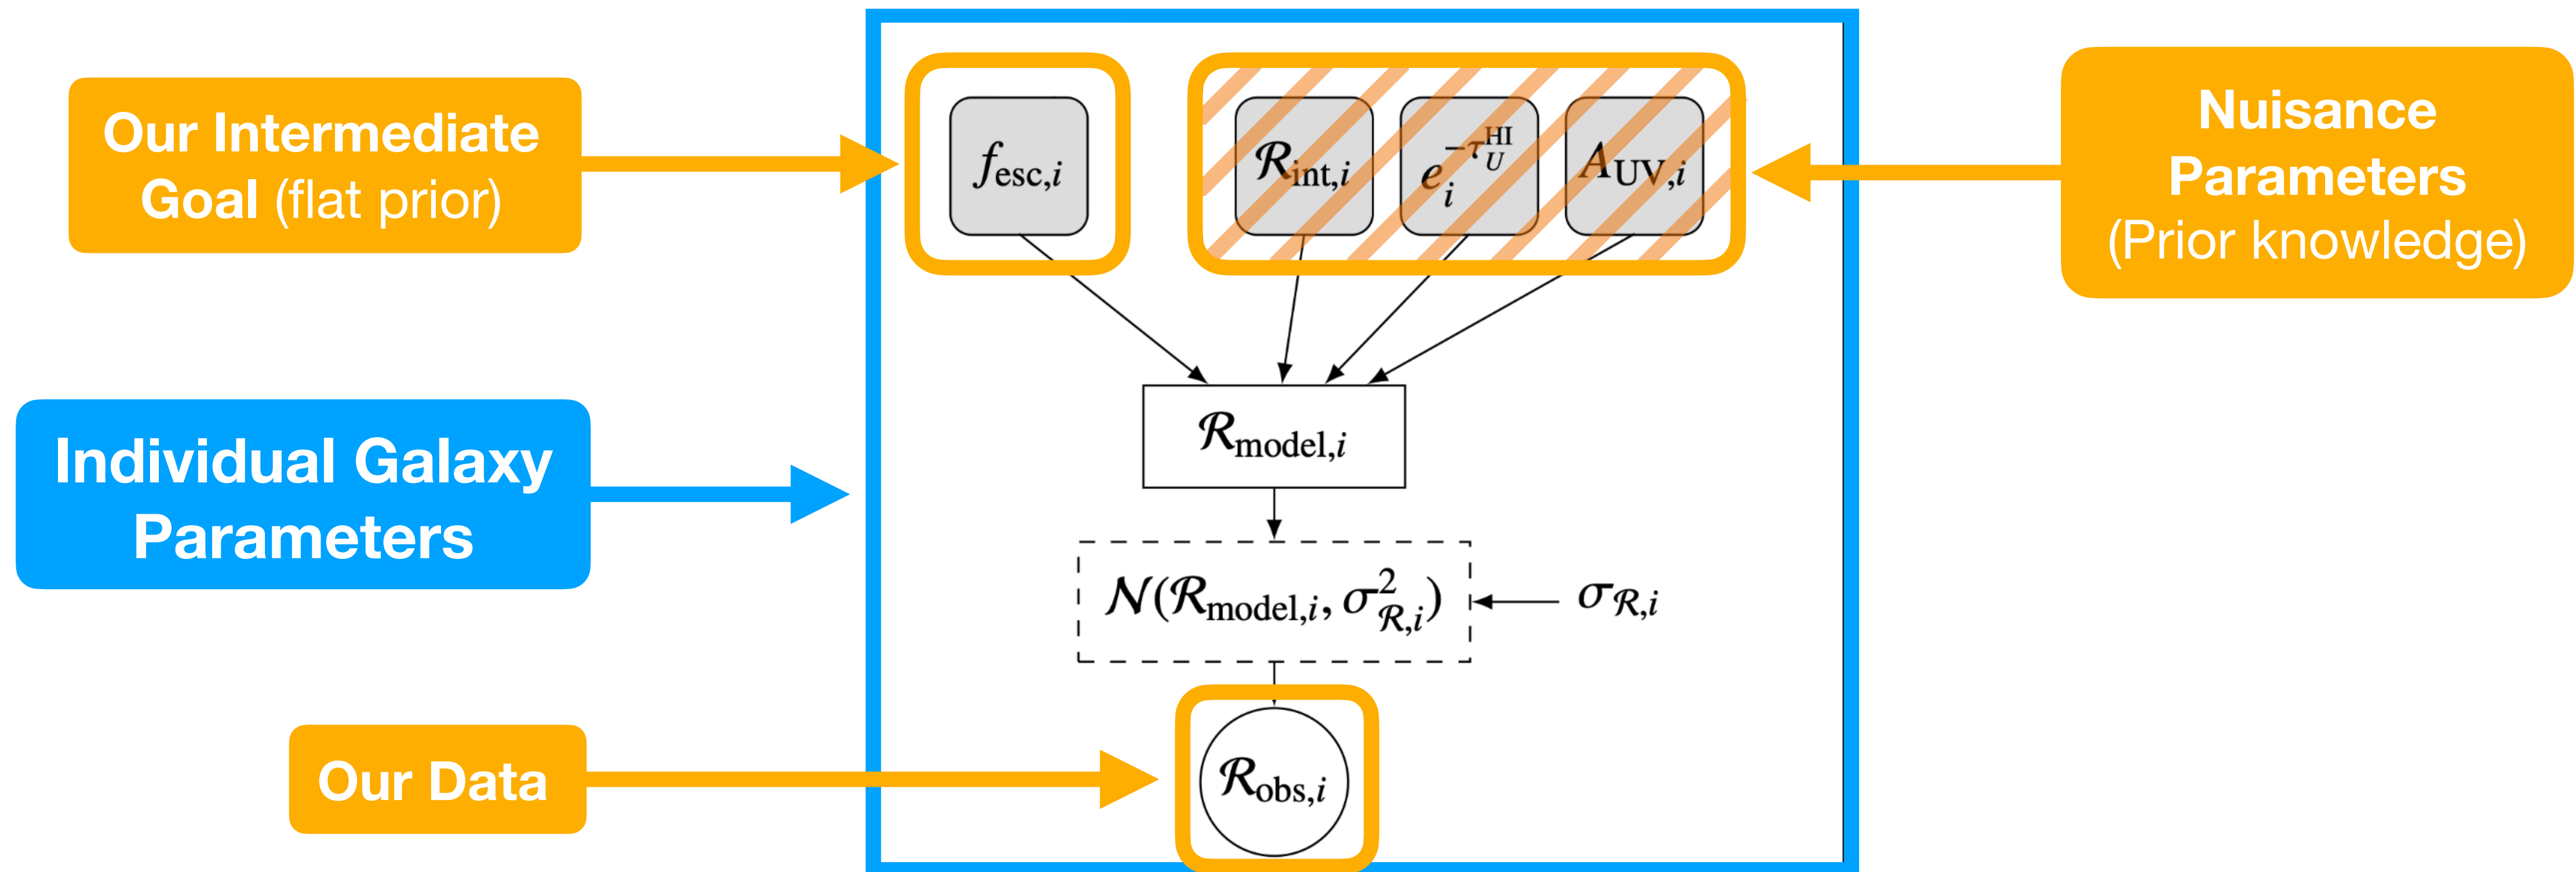

$$\mathcal{R}_{\text{obs}} = \left(\frac{L_{\text{LyC}}}{L_{\text{UV}}} \right)_{\text{obs}} = \left(\frac{\langle f_{\text{U}} \rangle}{\langle f_{\text{V606}} \rangle} \right)_{\text{obs}}$$

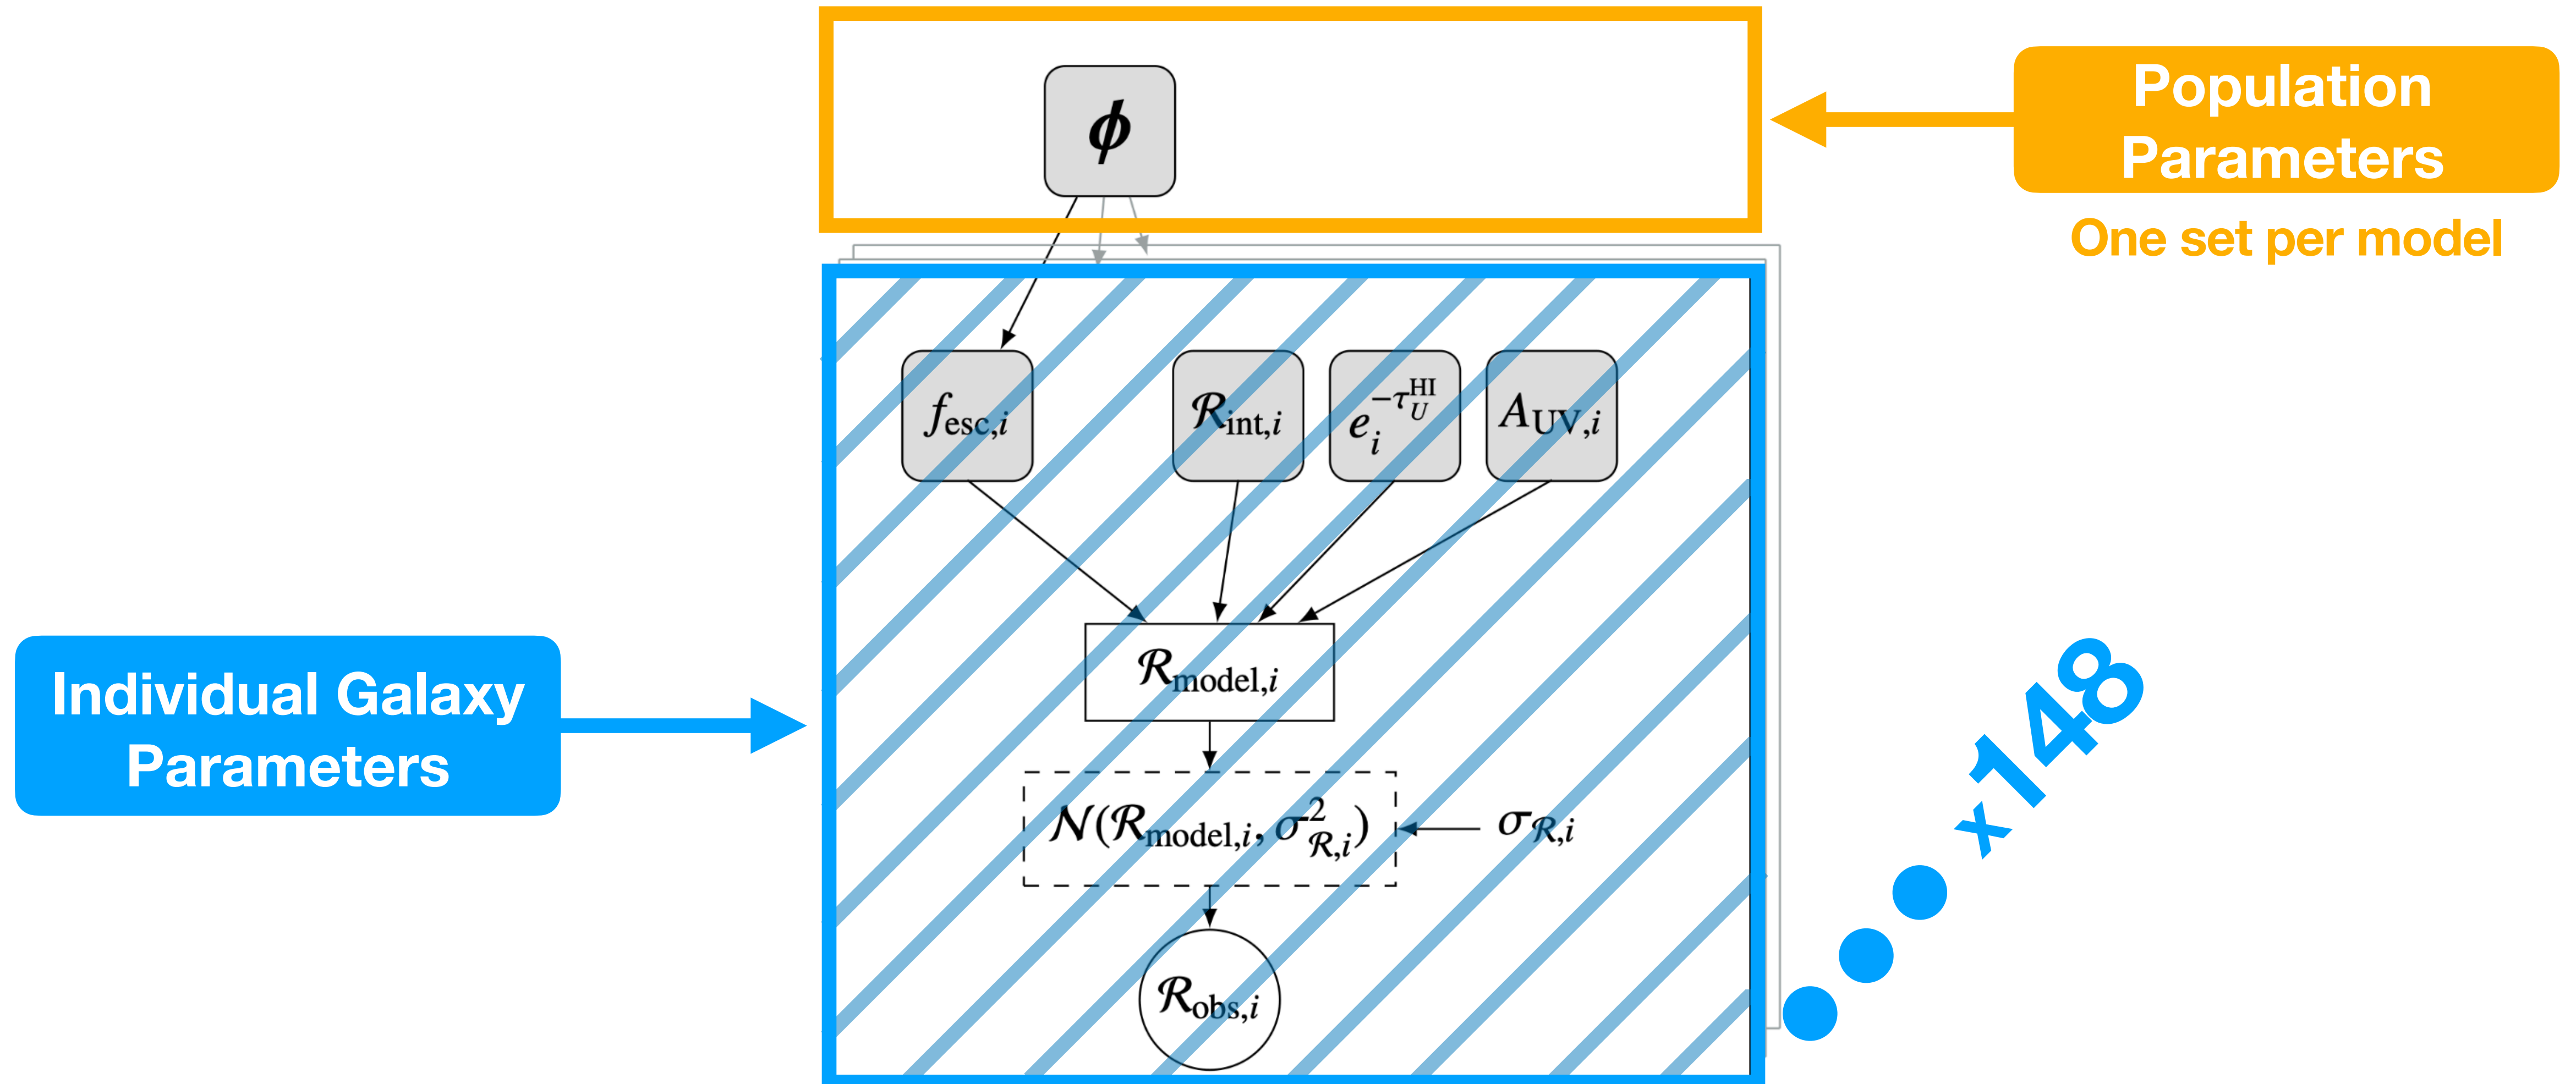

Linking the escape fraction to the data

How do we infer the population distribution?

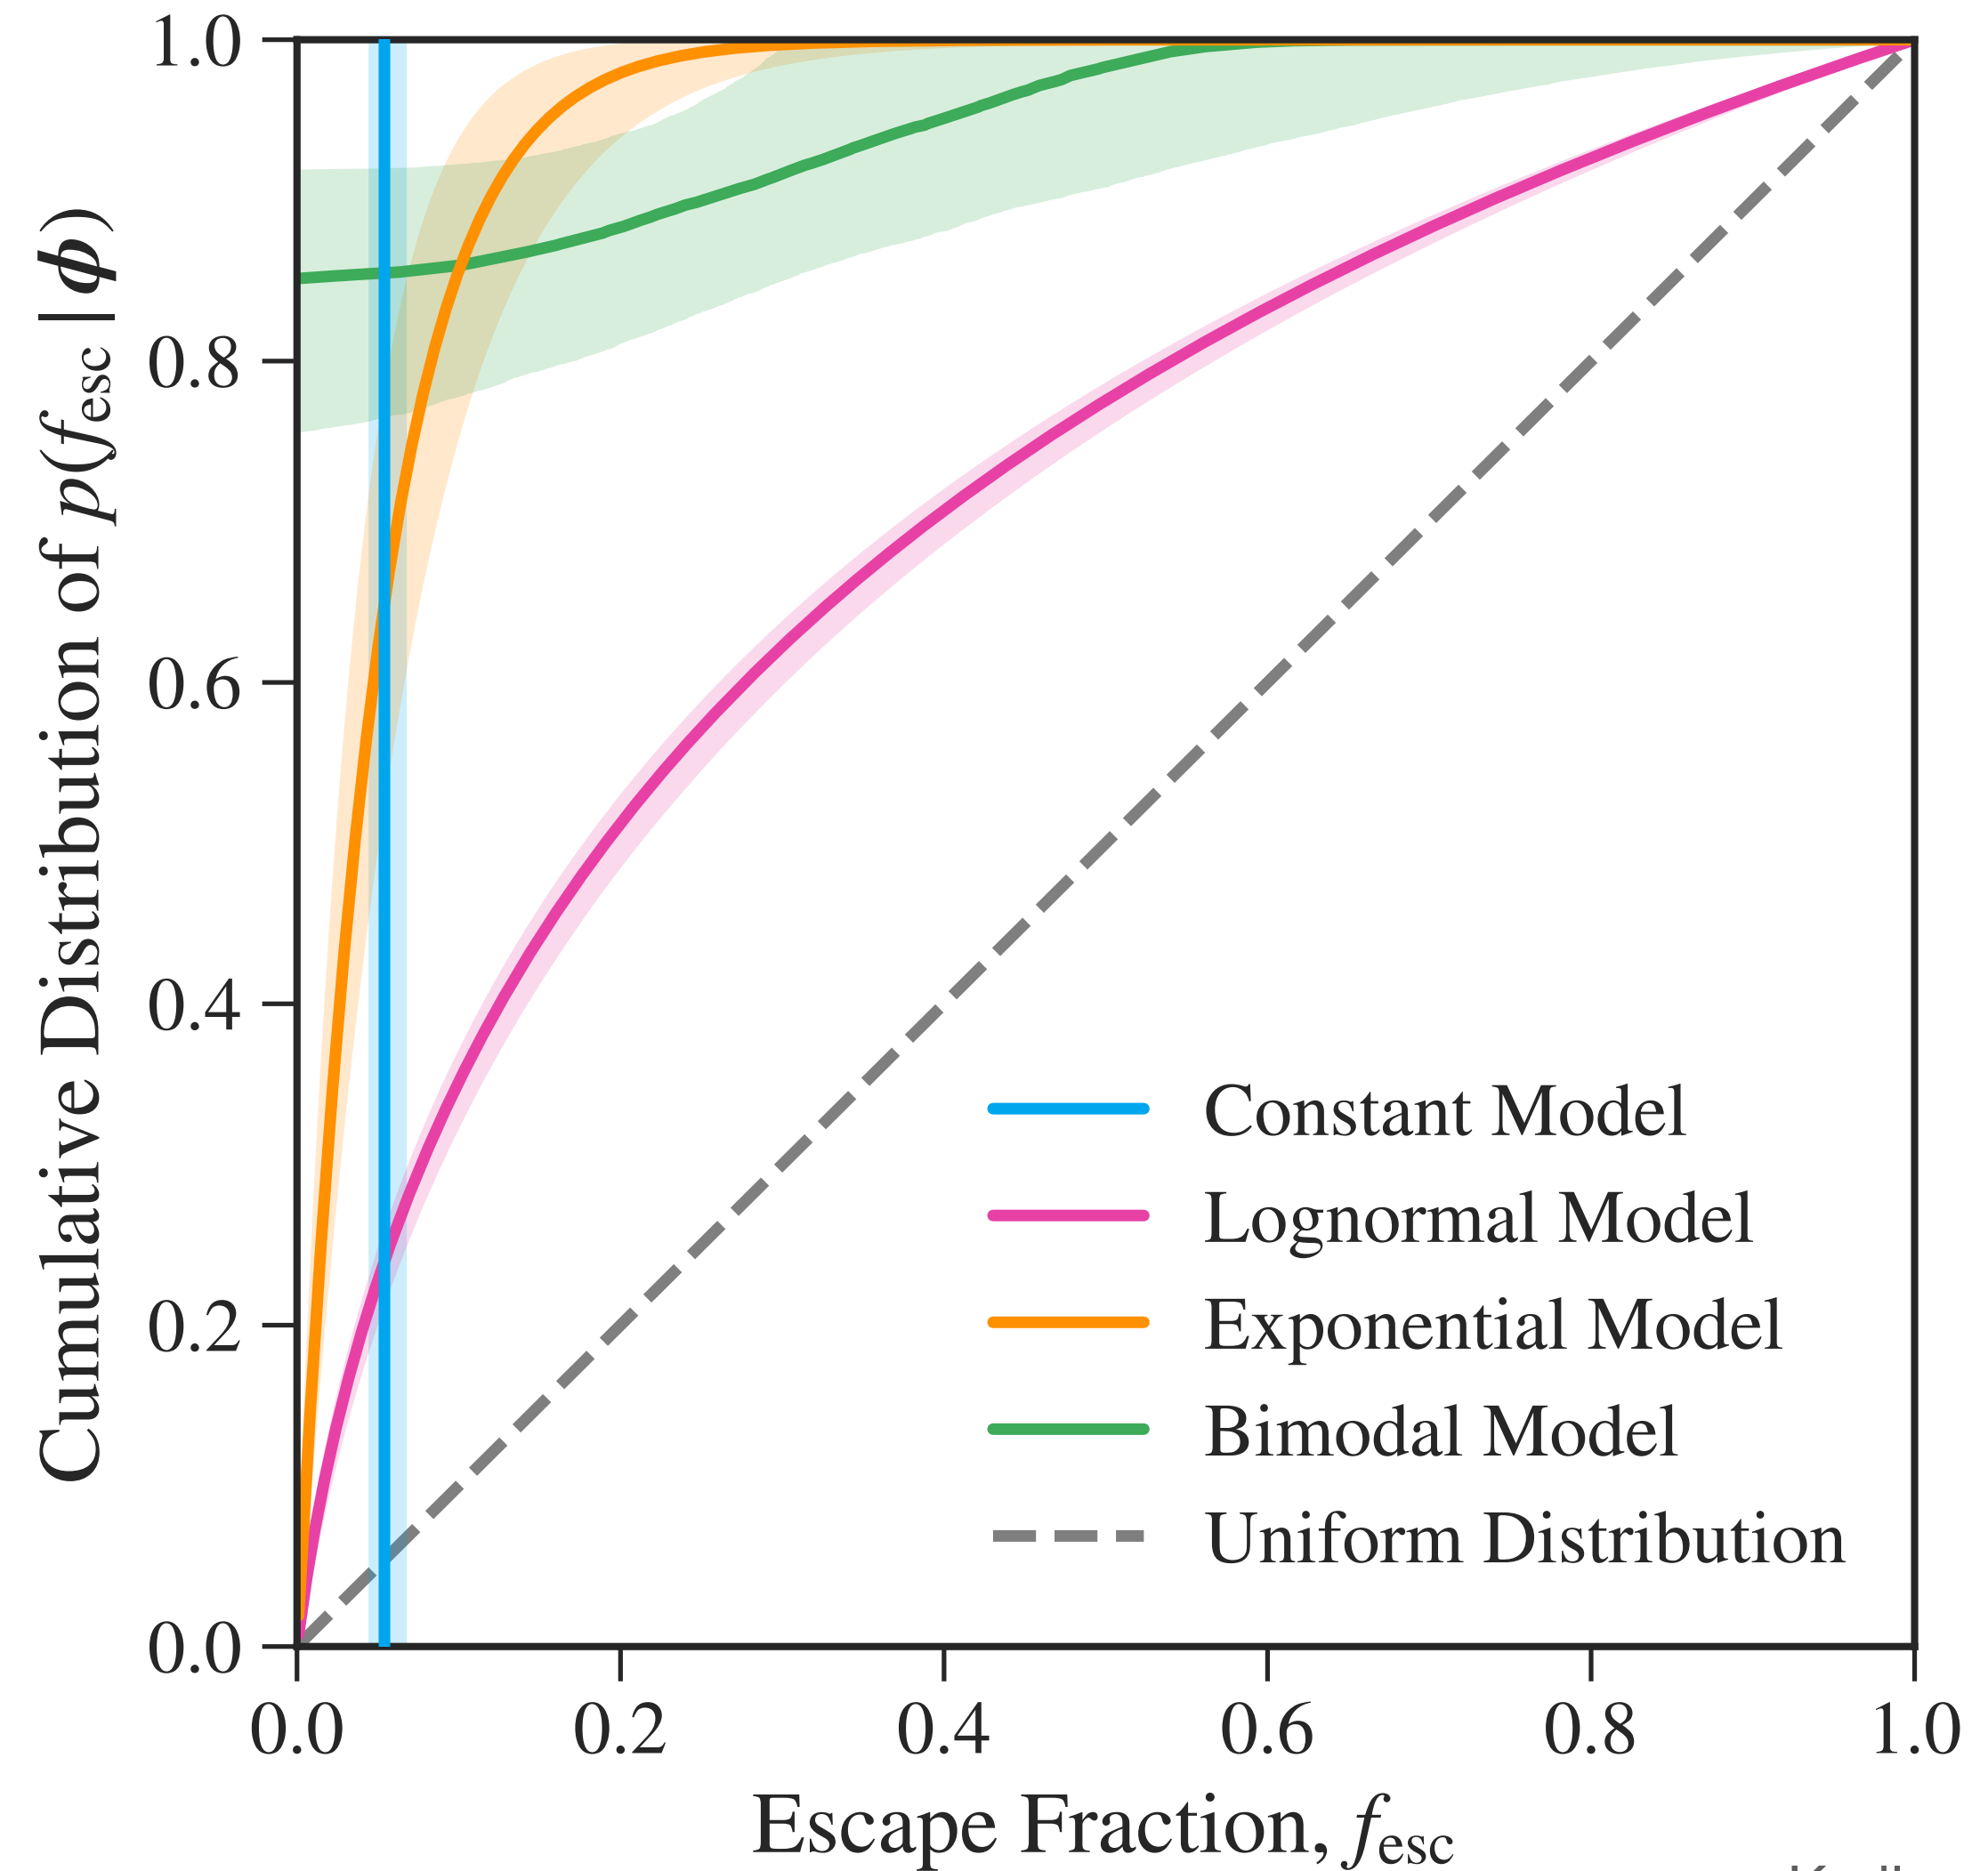

How do we infer the population distribution?

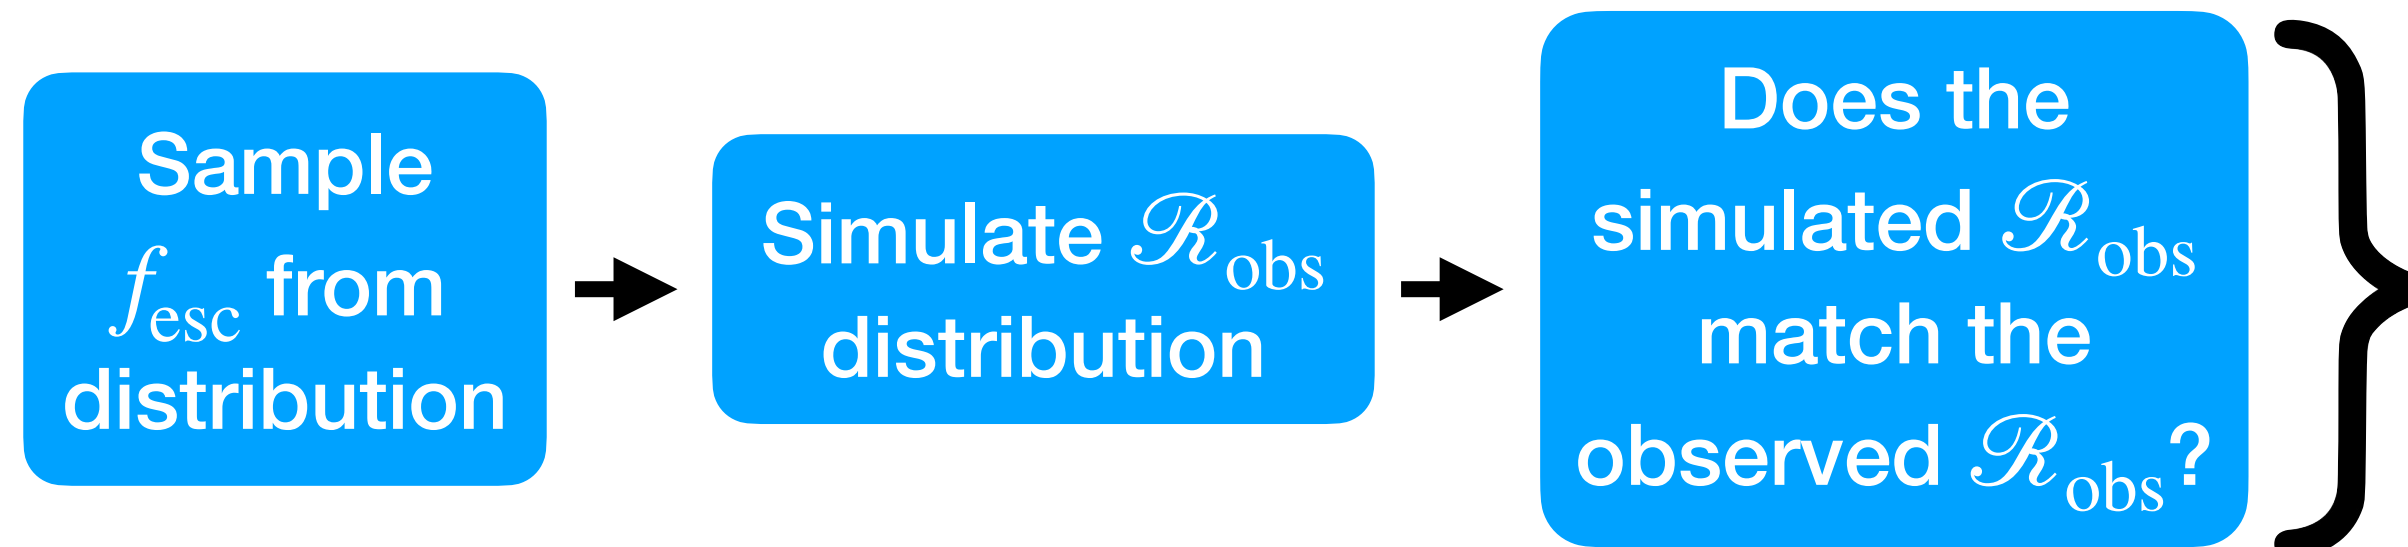

What does the distribution look like?

- Most distributions predict the majority of galaxies with: $f_{\text{esc}} < 0.1$

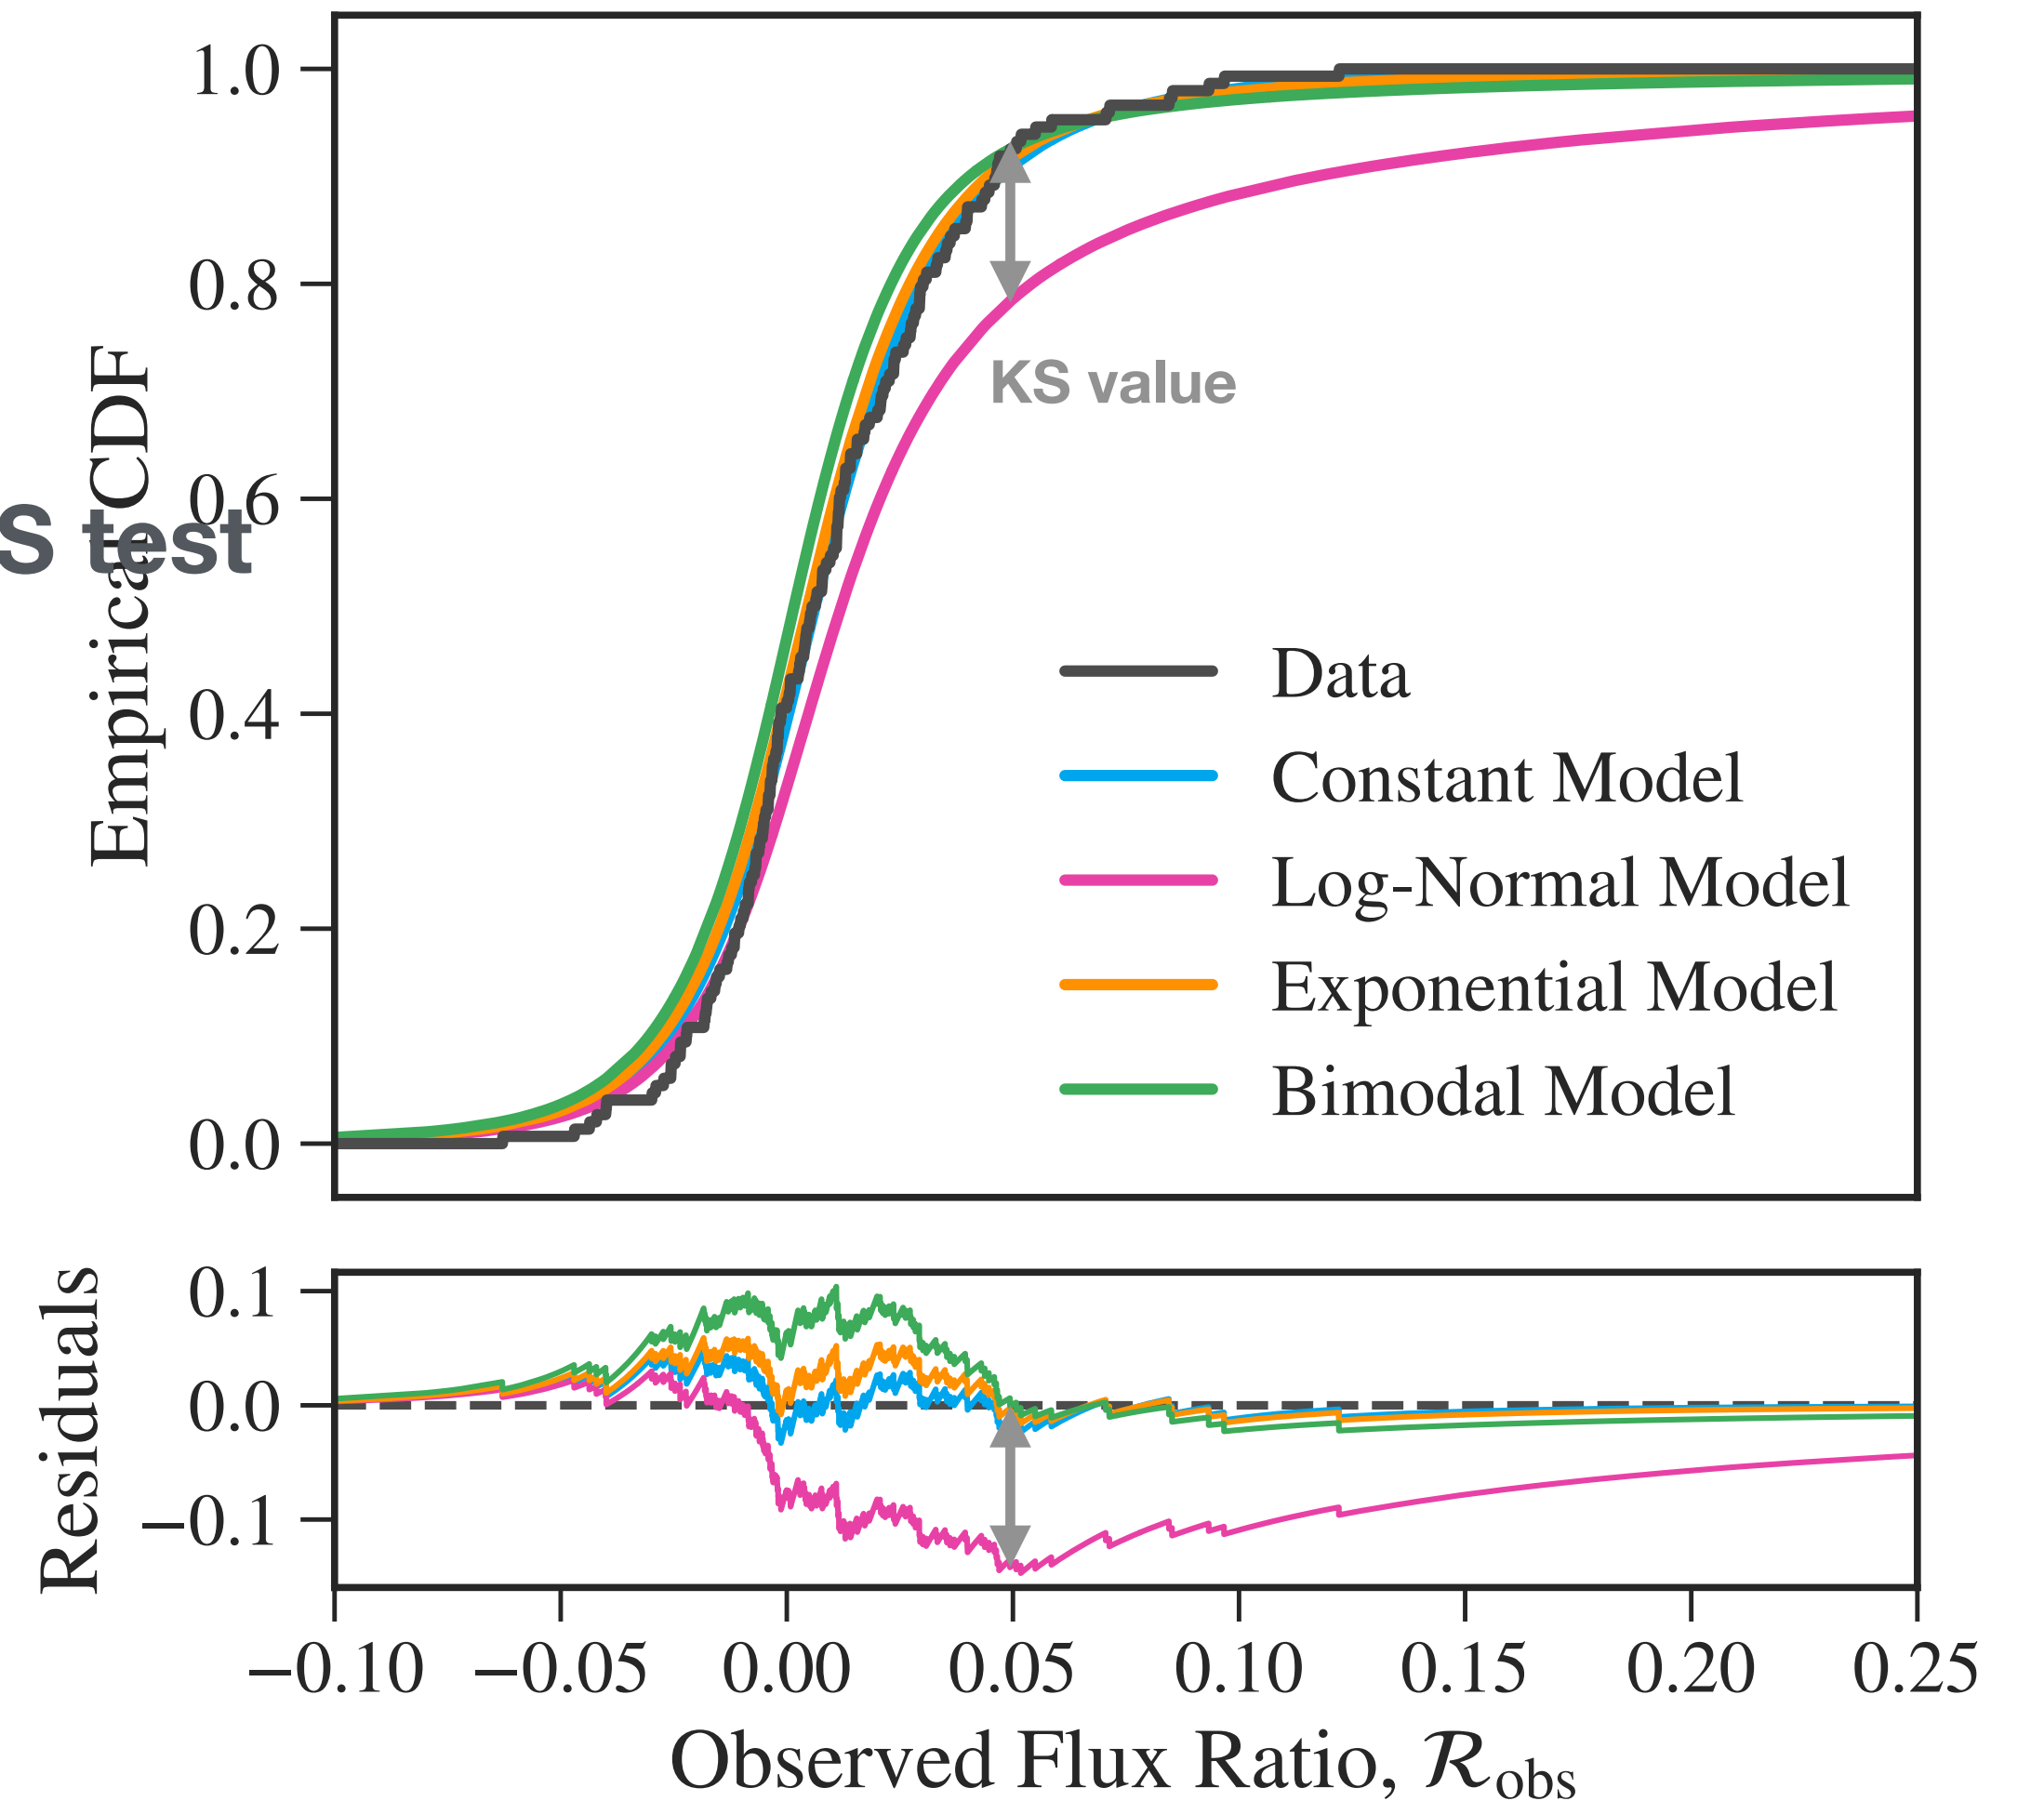

Which distribution is best?

Posterior Predictive Test

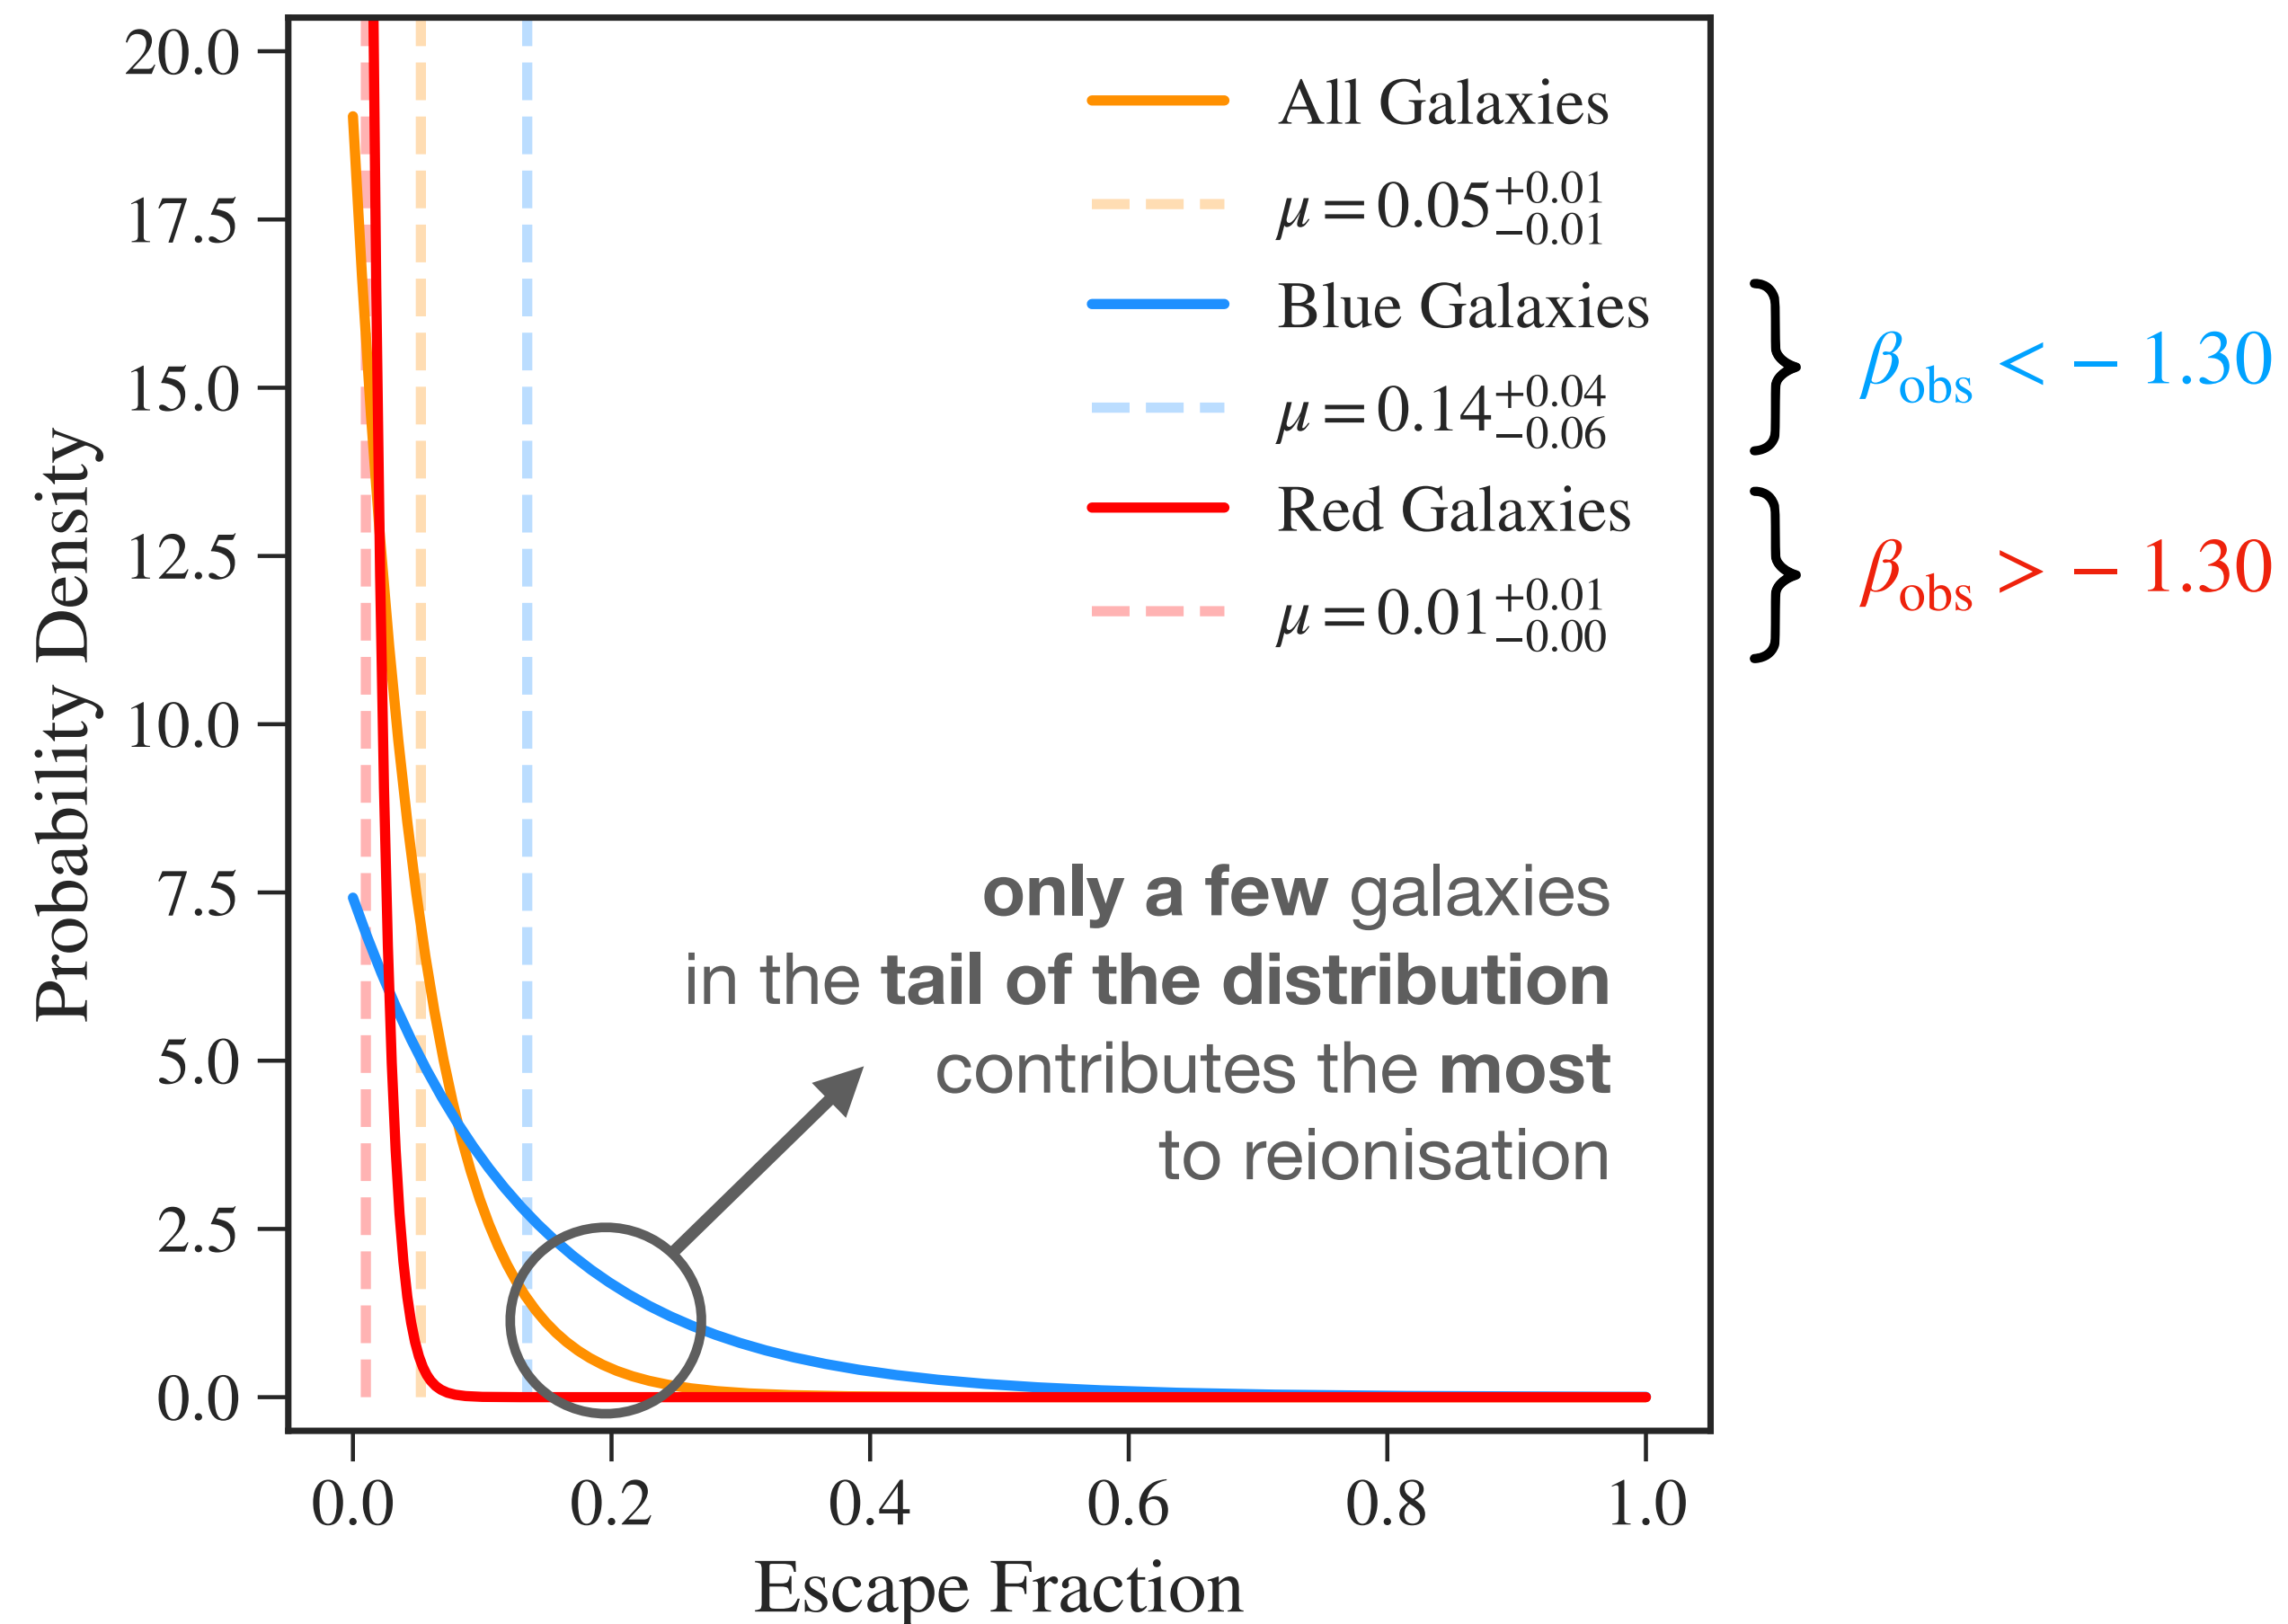

- We reject the log-normal + bimodal models.
- The constant model is inconsistent with individual measurements
- **The exponential distribution of f_{esc} is best**

What does the exponential PDF look like?

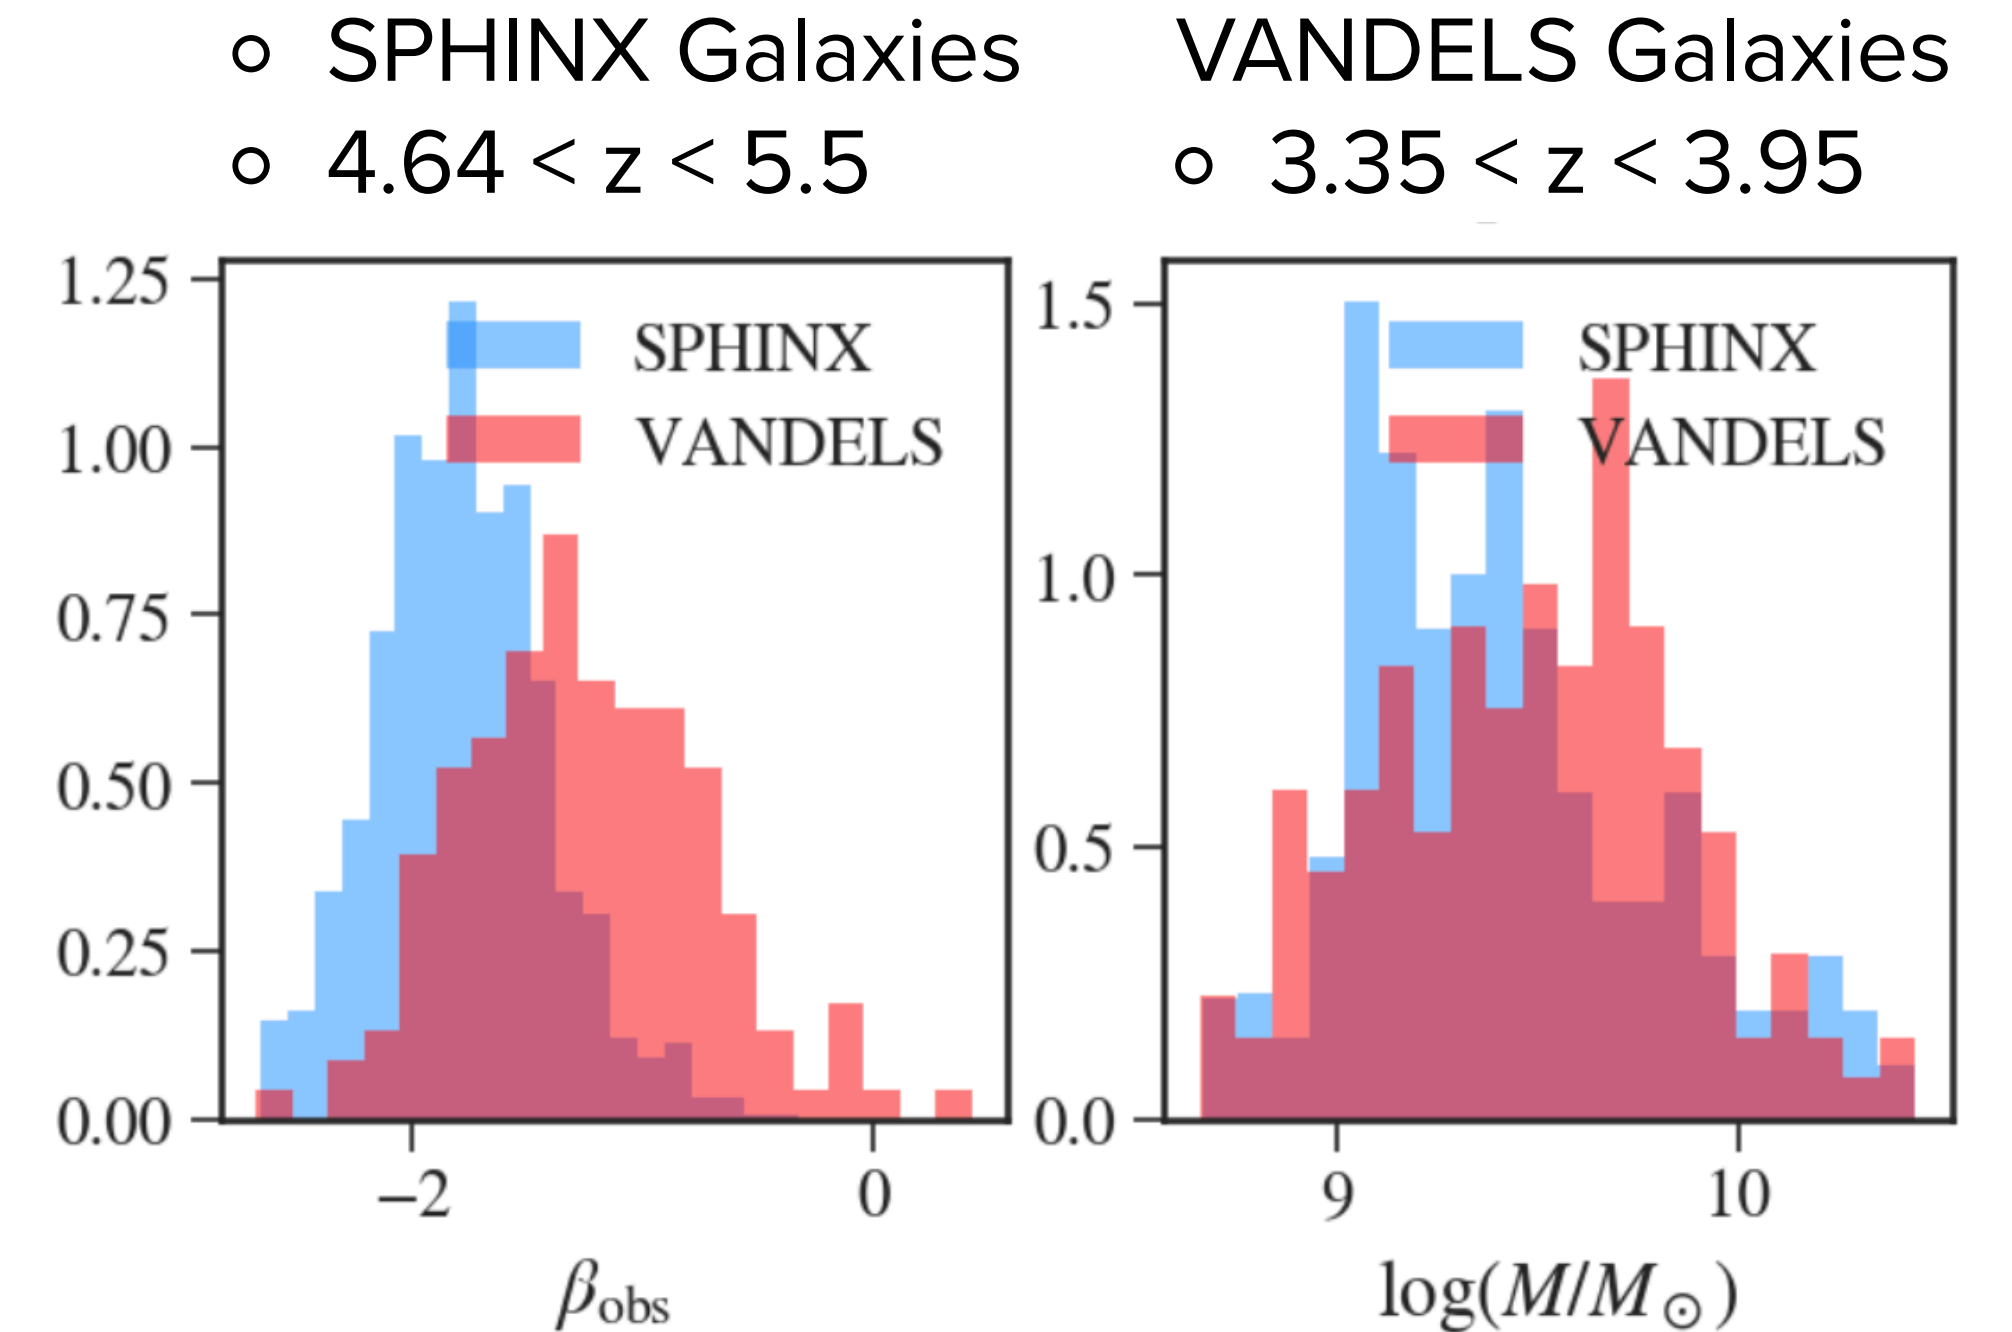

... it correlates with the UV beta slope

Comparing with simulations

... is challenging, but important!

- Fair comparison requires similar galaxies (redshift, mass, beta-slope, ...)
- Simulations and observations measure f_{esc} differently
- Sight line f_{esc} versus angle averaged f_{esc}

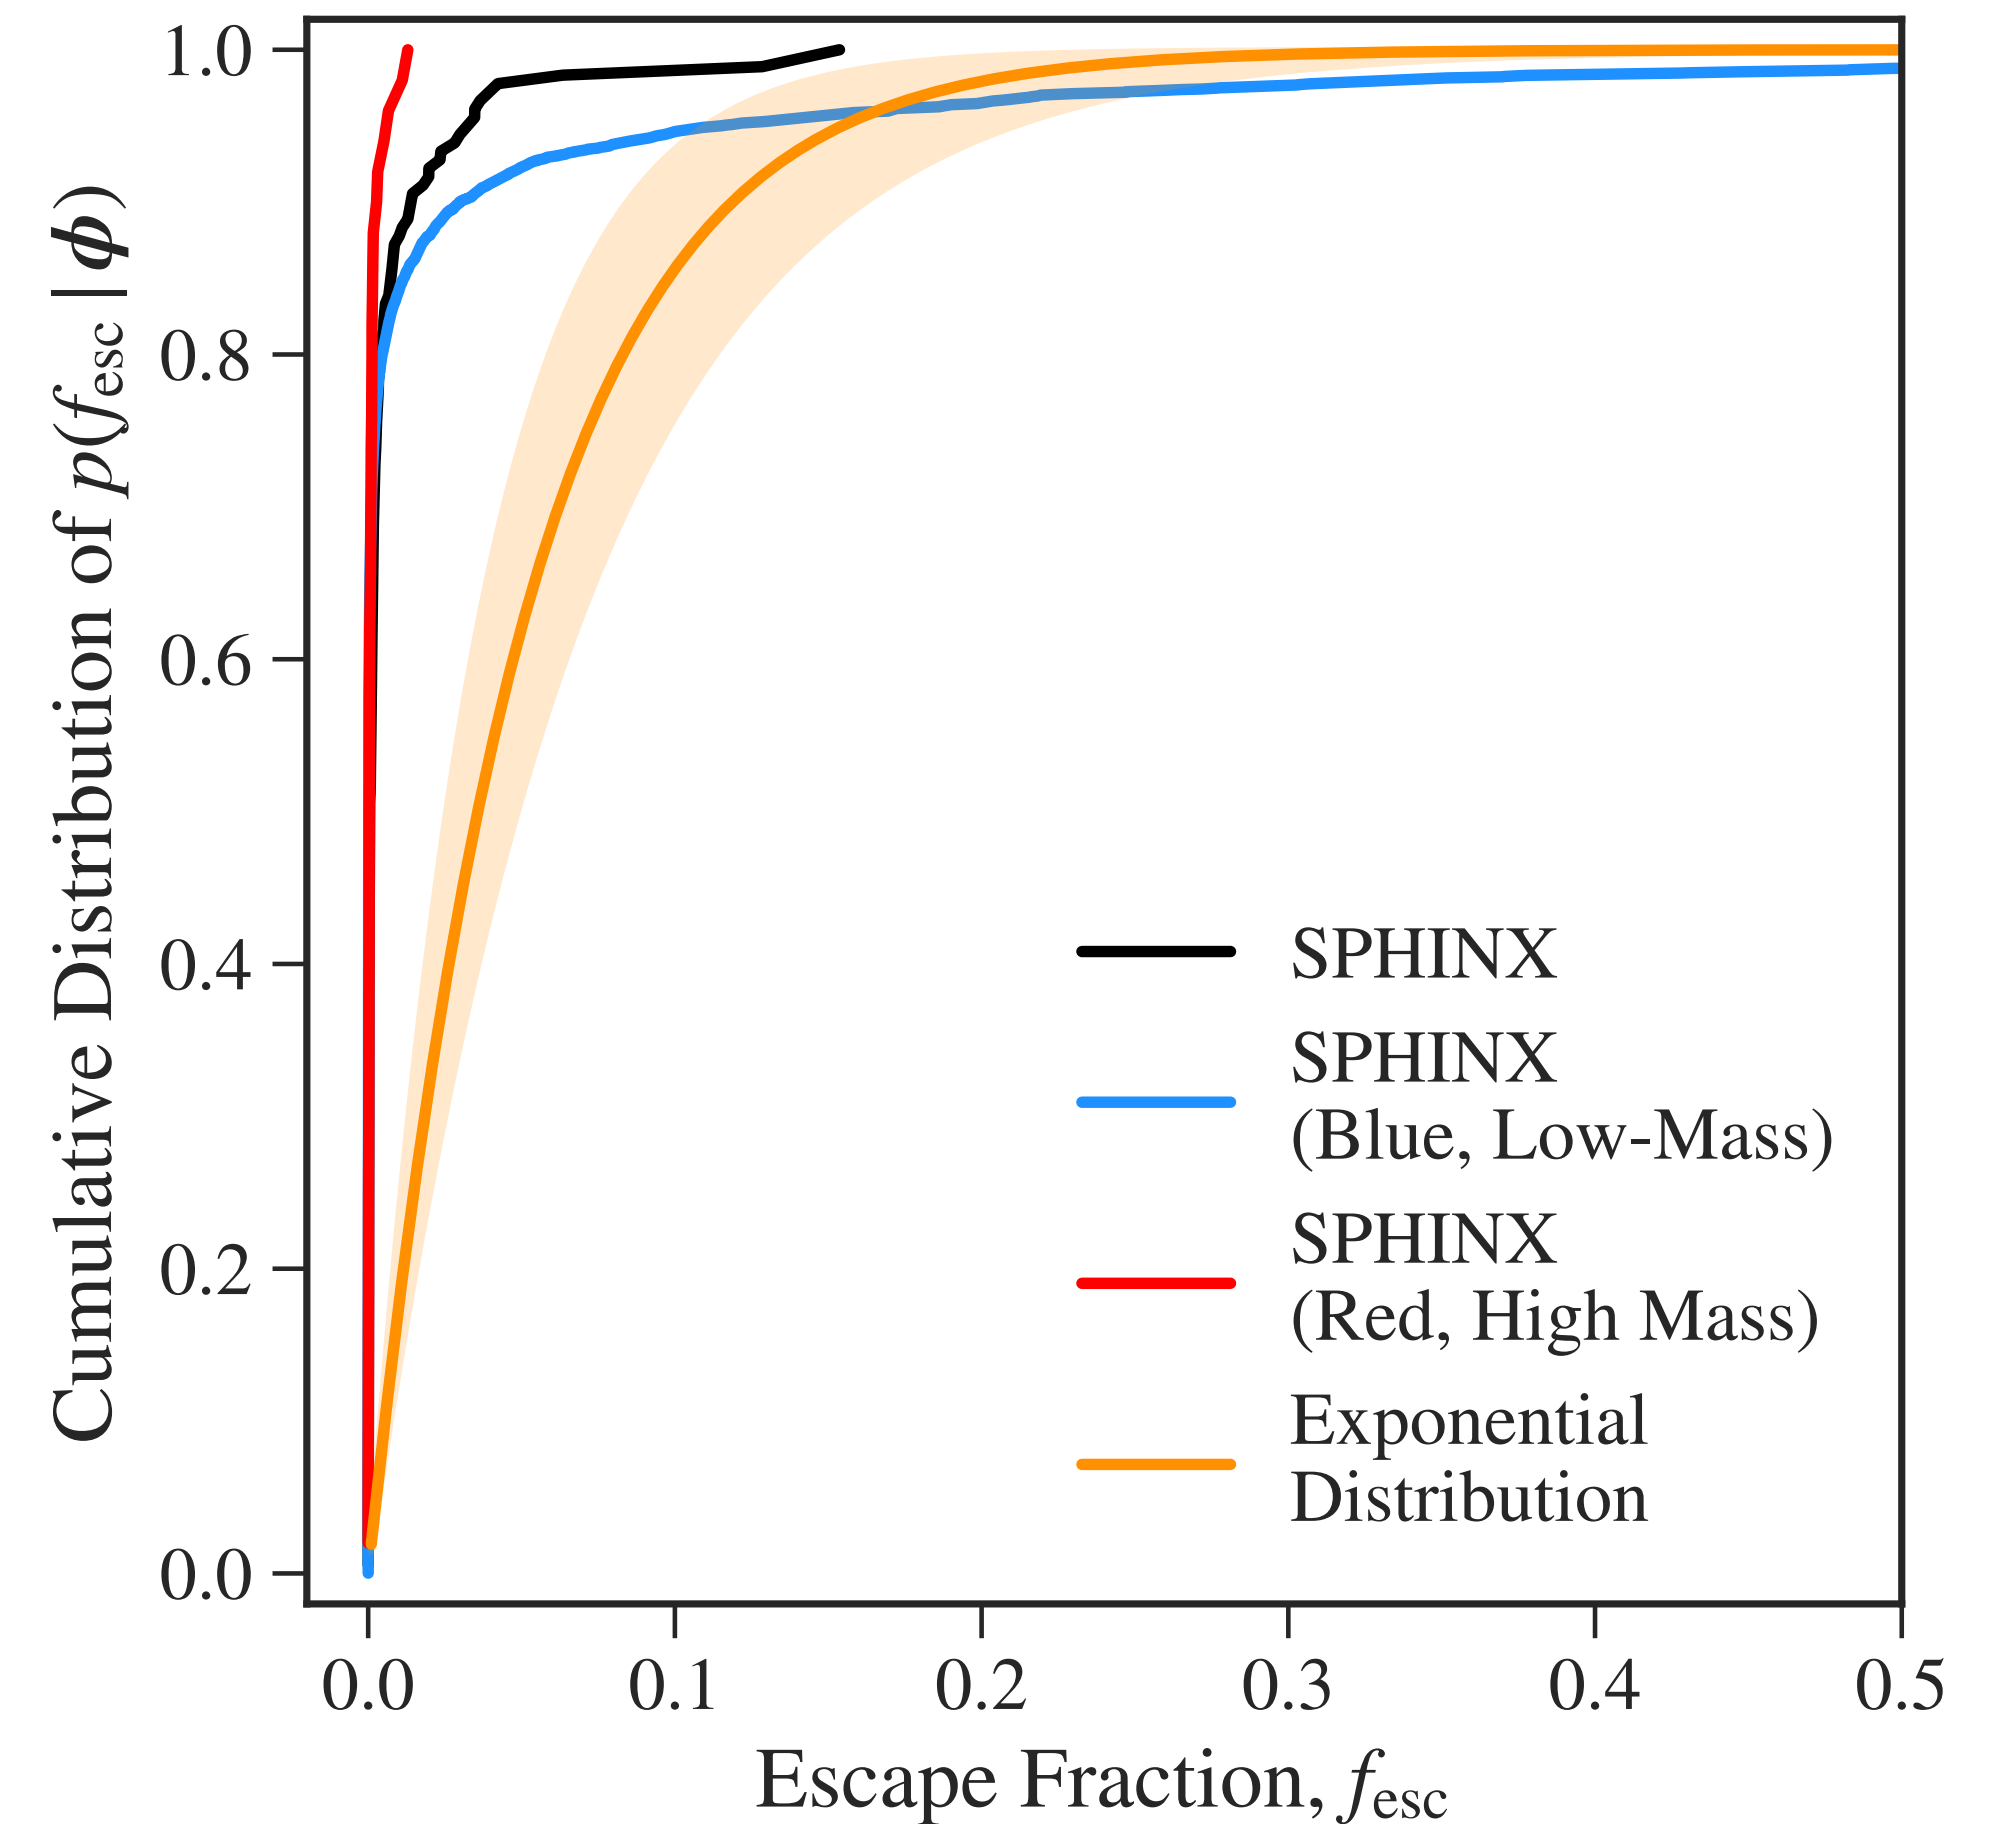

Comparing with simulations

... is challenging, but important!

- Fair comparison requires similar galaxies (redshift, mass, beta-slope, ...)
- Simulations and observations measure f_{esc} differently
- Sight line f_{esc} versus angle averaged f_{esc}

Somewhat similar shape, but the simulation under-predicts the escape fraction.

BEACON is:

- Pure-parallel multi-band imaging survey
- ~ 220 sightlines
- ~ 0.6 square degrees total area
- Awarded ~ 600 hours

BEACON will find:

- $N > 1e3$ galaxies at $z = 7-9$
- $N \sim 100$ galaxies at $z = 10 - 12$
- $N \sim 1-100$ galaxies at $z > 13$

A good $z \sim 10$ candidate

- NIRCAM 8-band imaging provides robust photometric redshift determination
- With our 8 band filter configurations we can determine redshifts at $z \sim 2$ up to $z > 10$

Take Aways

FESC DISTRIBUTION

arXiv: 2405.10364

- We recover **expected values of $f_{\text{esc}} = 0.05$** consistent w. previous work (Begley+2022)
- We argue the distribution is exponential: **only a small fraction of sources may be the main contributors to reionisation at a given time.**
- **Correlation with physical galaxy properties is possible** with more data, useful for constraints within EoR

BEACON SURVEY

Morishita+ in prep.

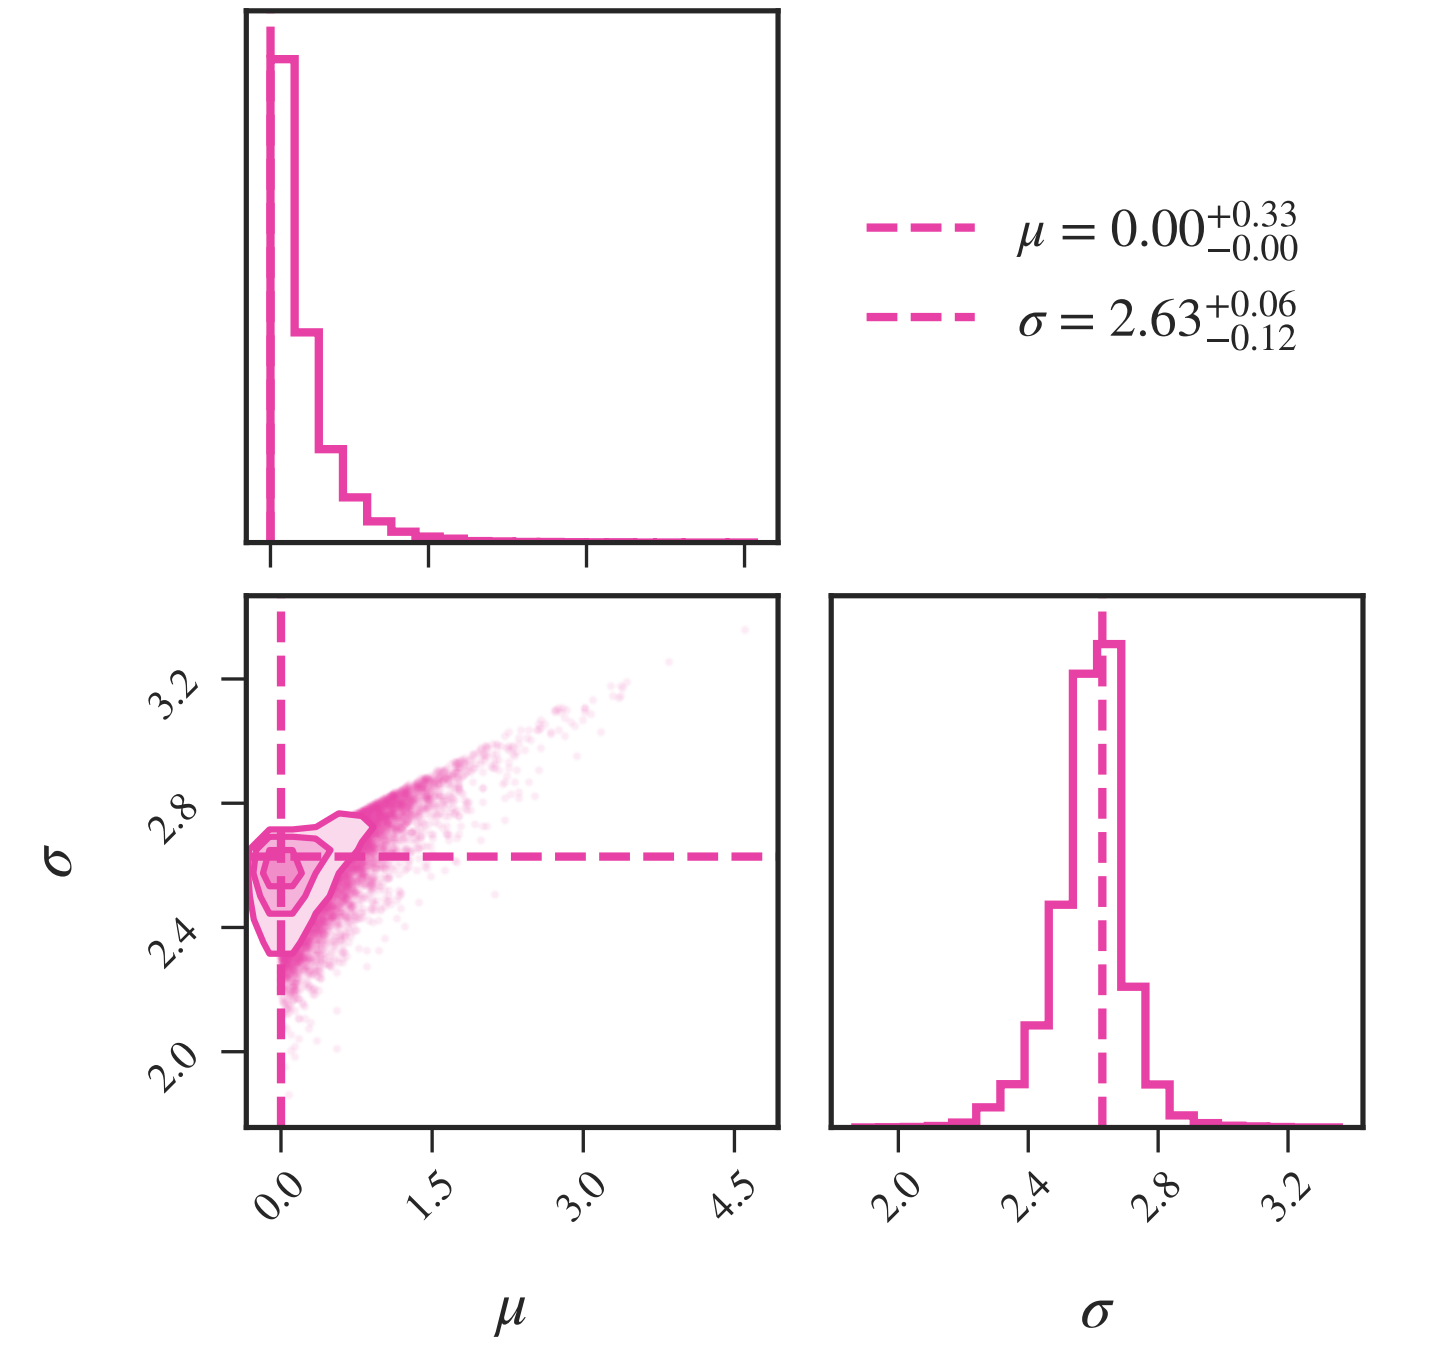

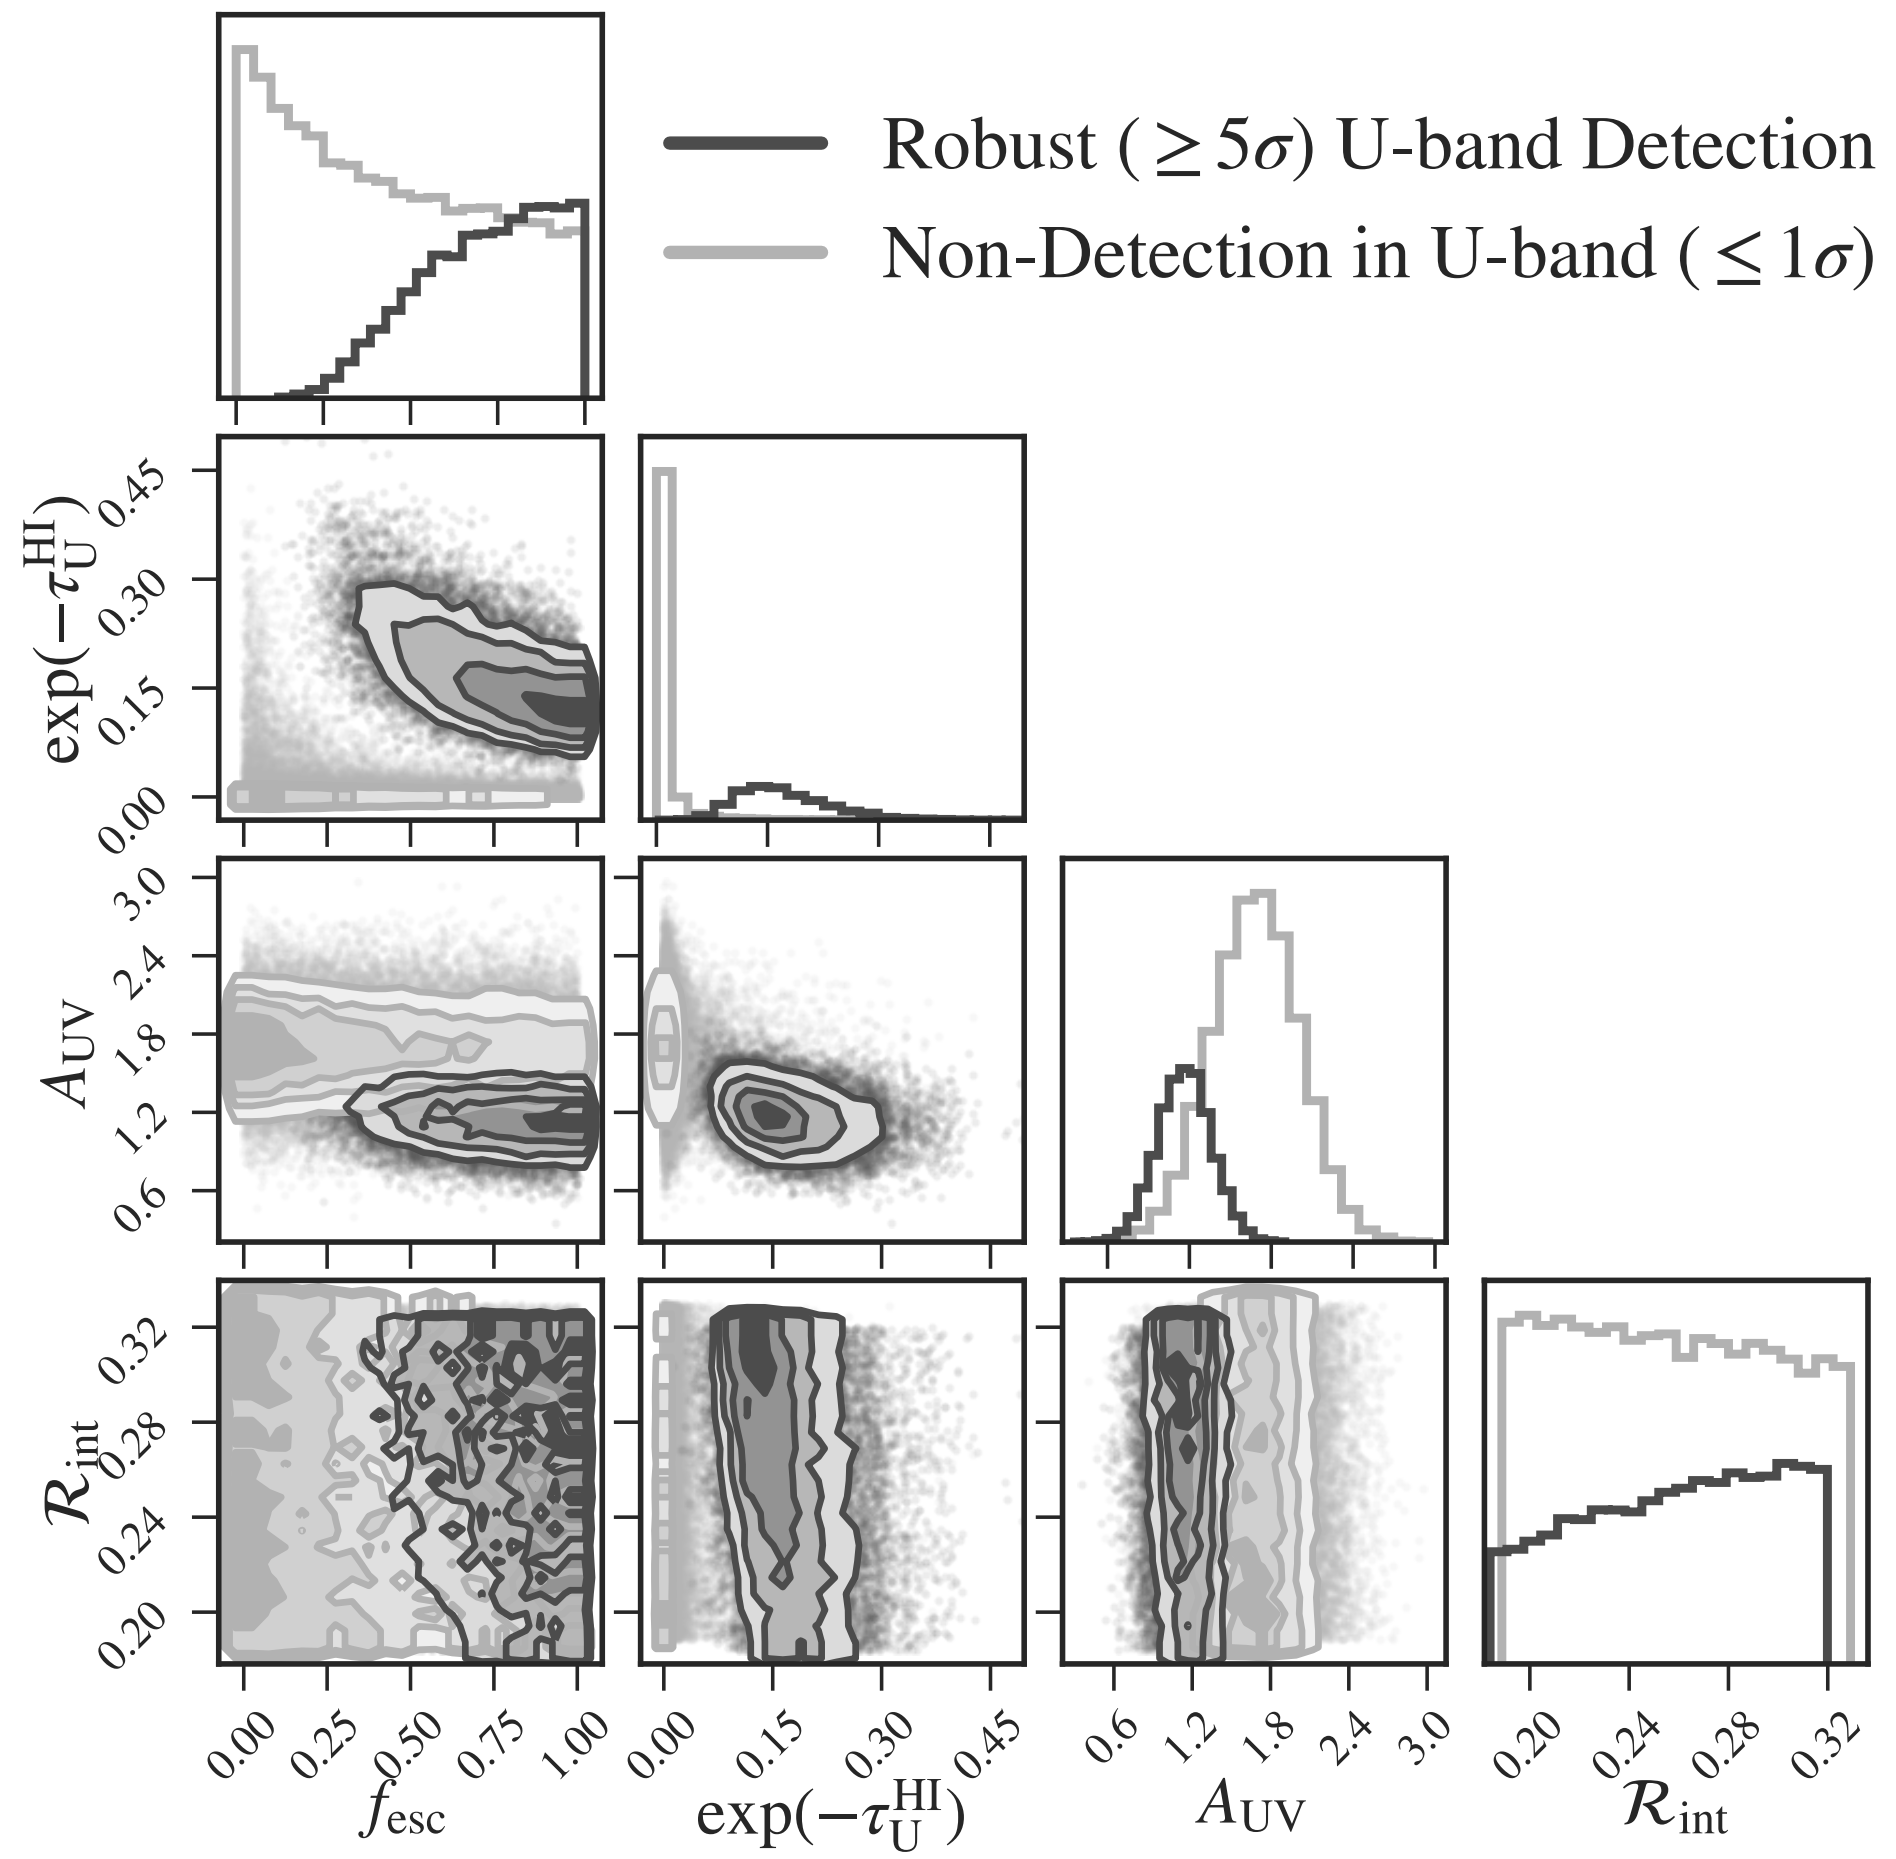

- **Unbiased** view of the Universe
- **Robust photometric redshifts**
- Candidates for spectroscopic follow-up
- Pure-Parallel is “free”
