

# How useful are simulations for understanding the sources of reionization?

Can we predict the escape of LyC radiation from galaxies with simulations?

**Joki Rosdahl**

CENTRE DE RECHERCHE ASTROPHYSIQUE DE LYON

**Cosmic Dawn at high latitudes, June 2024**

# What are the sources of reionization?

*Most likely* massive young stars emitting ionising radiation that **leaks** out of the inter-stellar medium (ISM) of galaxies

Knowing the emissivity of these young stars in the early Universe allows us to model reionization:

$$\frac{dQ_{\text{HII}}}{dt} = \frac{\dot{n}_{\text{ion}}}{\langle n_{\text{H}} \rangle} - \frac{Q_{\text{HII}}}{\langle t_{\text{rec}} \rangle}$$

Diagram illustrating the equation for the rate of change of ionizing photon production rate ( $dQ_{\text{HII}}/dt$ ) in the early Universe:

- $\frac{dQ_{\text{HII}}}{dt}$ : rate of change of ionizing photon production rate
- $\dot{n}_{\text{ion}}$ : emissivity per volume of ionising photons
- $\langle n_{\text{H}} \rangle$ : average density of IGM
- $Q_{\text{HII}}$ : ionizing photon production rate
- $\langle t_{\text{rec}} \rangle$ : recombination time
- Volume-filling factor of HII is indicated by an arrow pointing to the left side of the equation.

# What are the sources of reionization?

$$\frac{dQ_{\text{HII}}}{dt} = \frac{\dot{n}_{\text{ion}}}{\langle n_{\text{H}} \rangle} - \frac{Q_{\text{HII}}}{\langle t_{\text{rec}} \rangle}$$

volume-filling factor of HII (points to  $dQ_{\text{HII}}/dt$ )  
 emissivity per volume of ionising photons (points to  $\dot{n}_{\text{ion}}$ )  
 average density of IGM (points to  $\langle n_{\text{H}} \rangle$ )  
 recombination time (points to  $\langle t_{\text{rec}} \rangle$ )

The main ingredient is the emission of radiation from galaxies

$$\dot{n}_{\text{ion}}(z) = \overset{\text{=known}}{SFRD(z)} \times \overset{\text{=known}}{\ell} \times f_{\text{esc}}(z)$$

star formation rate density (points to  $SFRD(z)$ )  
 number of photons per stellar mass formed (points to  $\ell$ )  
 escape fraction of ionising radiation from galaxies (points to  $f_{\text{esc}}(z)$ )

**Observed  $f_{\text{esc}}$  is very low at low  $z$ , and unknown at  $z \geq 5$  so almost a free parameter**  
**→ simulations are needed**

**Can we predict LyC escape fractions with simulations?**

**I: 'ancient' history**

# ESCAPE OF IONIZING RADIATION FROM HIGH-REDSHIFT GALAXIES

NICKOLAY Y. GNEDIN,<sup>1,2,3</sup> ANDREY V. KRAVTSOV,<sup>2,3,4</sup> AND HSIAO-WEN CHEN<sup>3</sup>

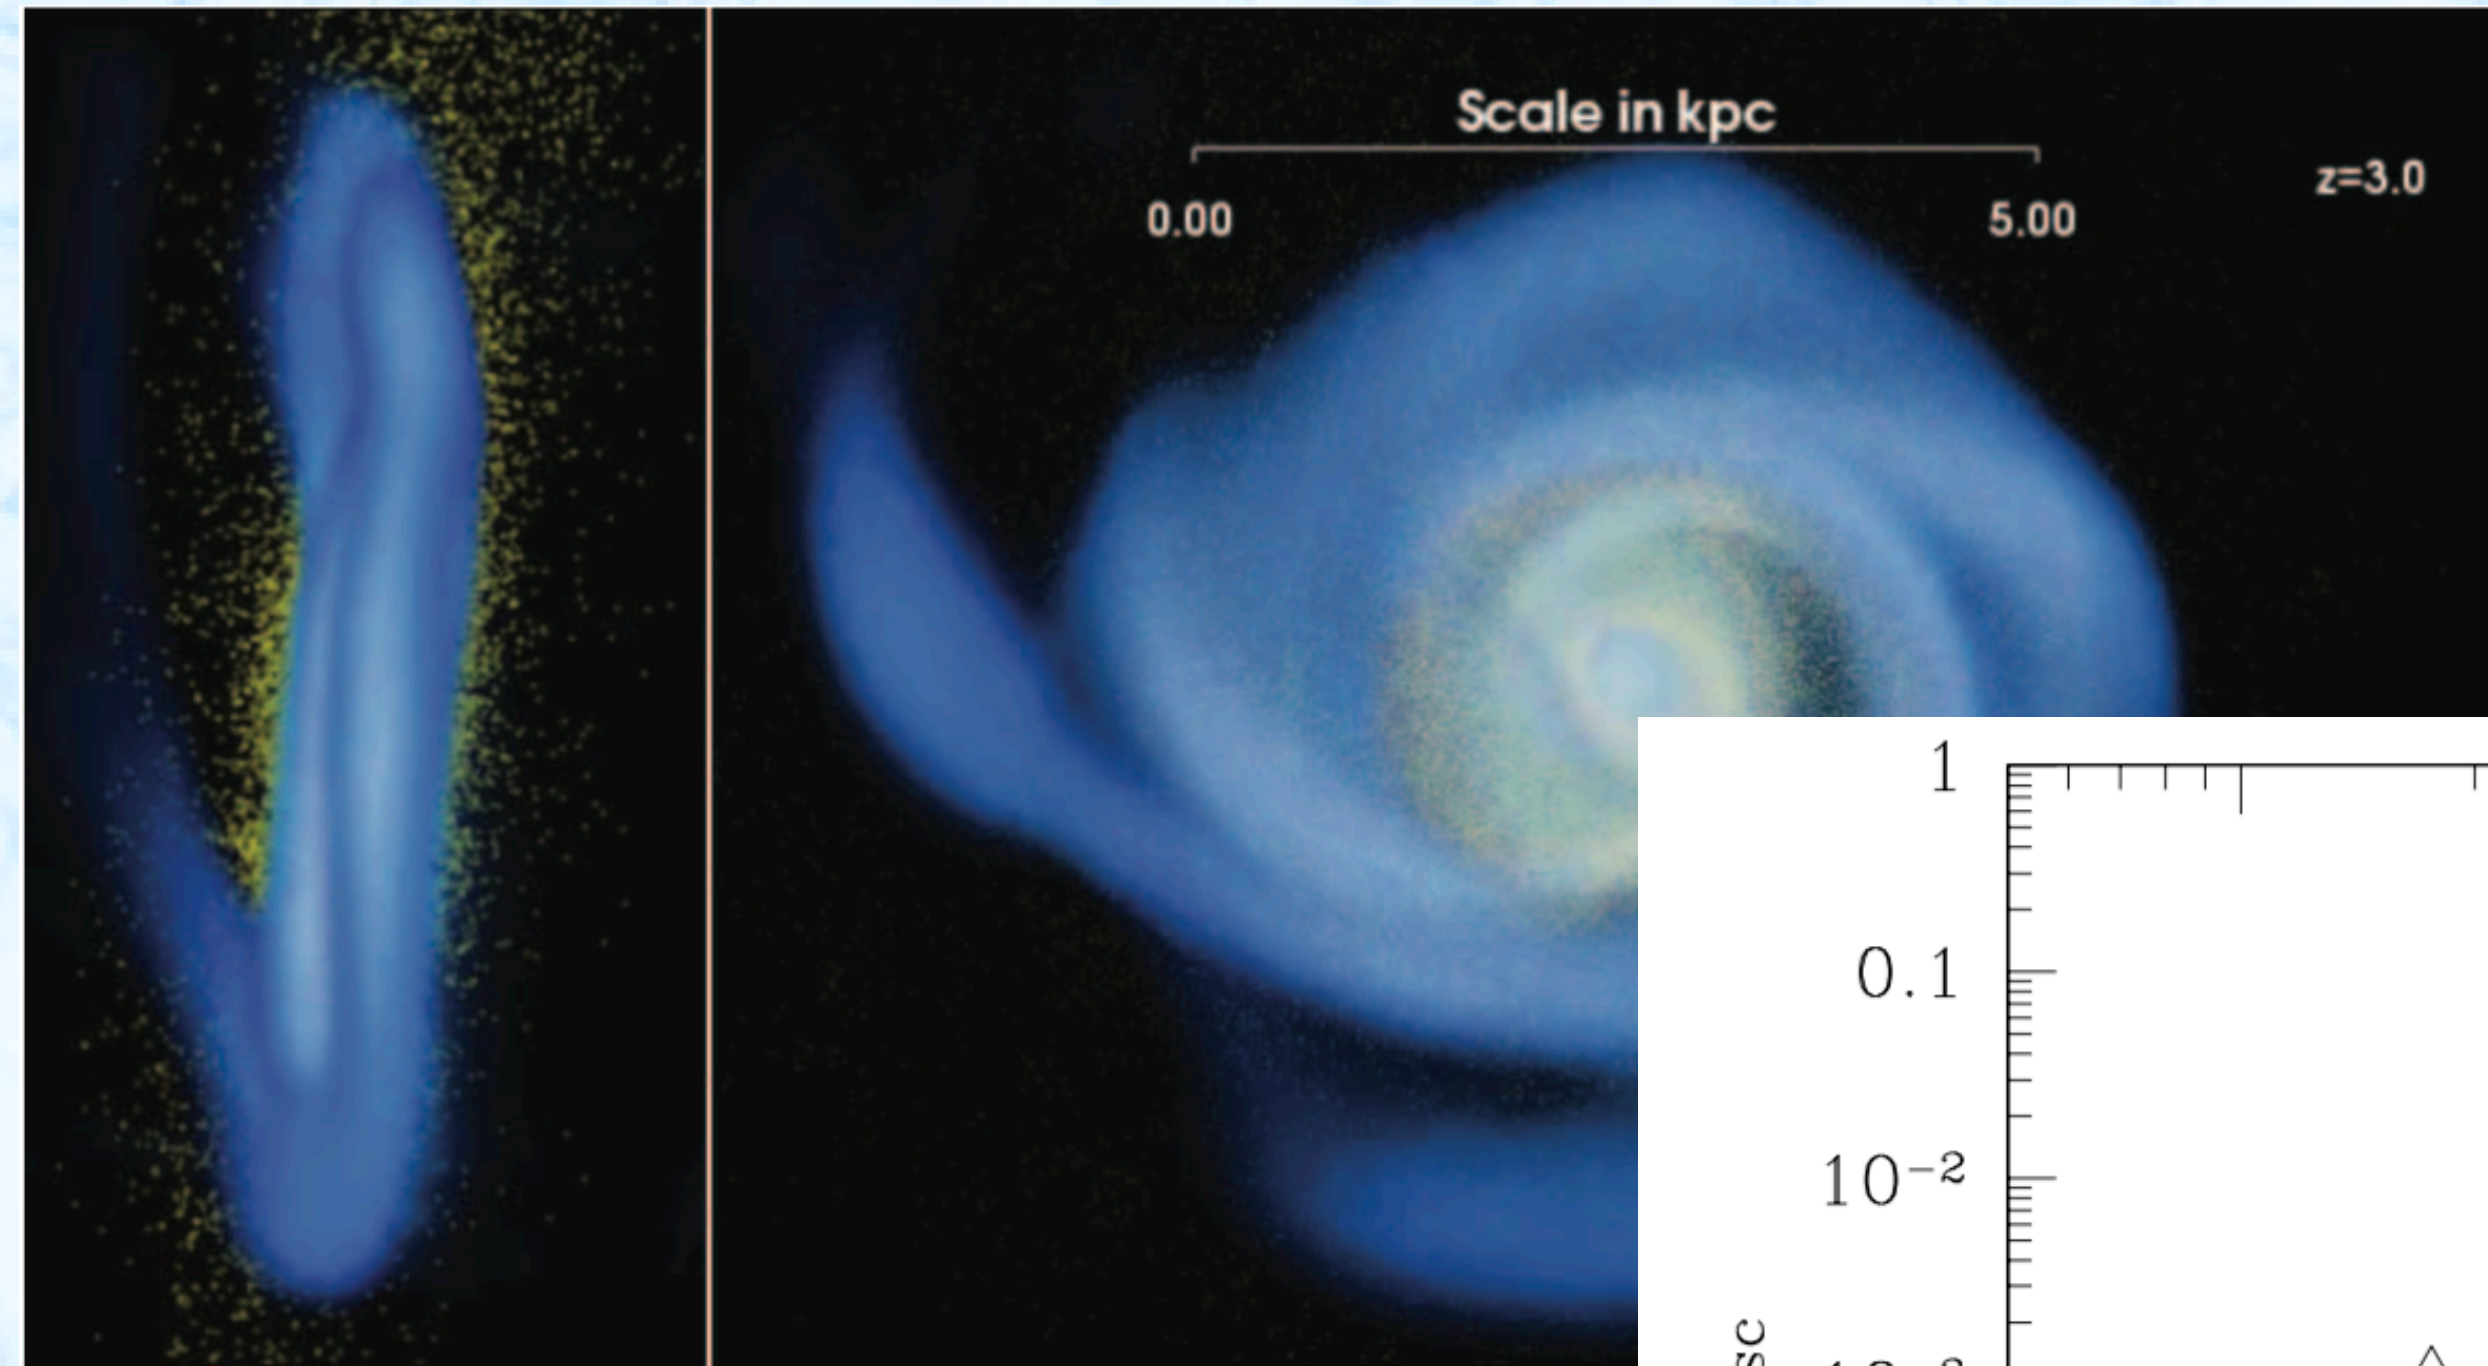

*Received 2007 July 6; accepted 2007 September 23*

Cosmological RHD zoom simulation

$M_{\text{halo}} \lesssim 10^{11} M_{\odot}$  at  $z=3$

Physical resolution

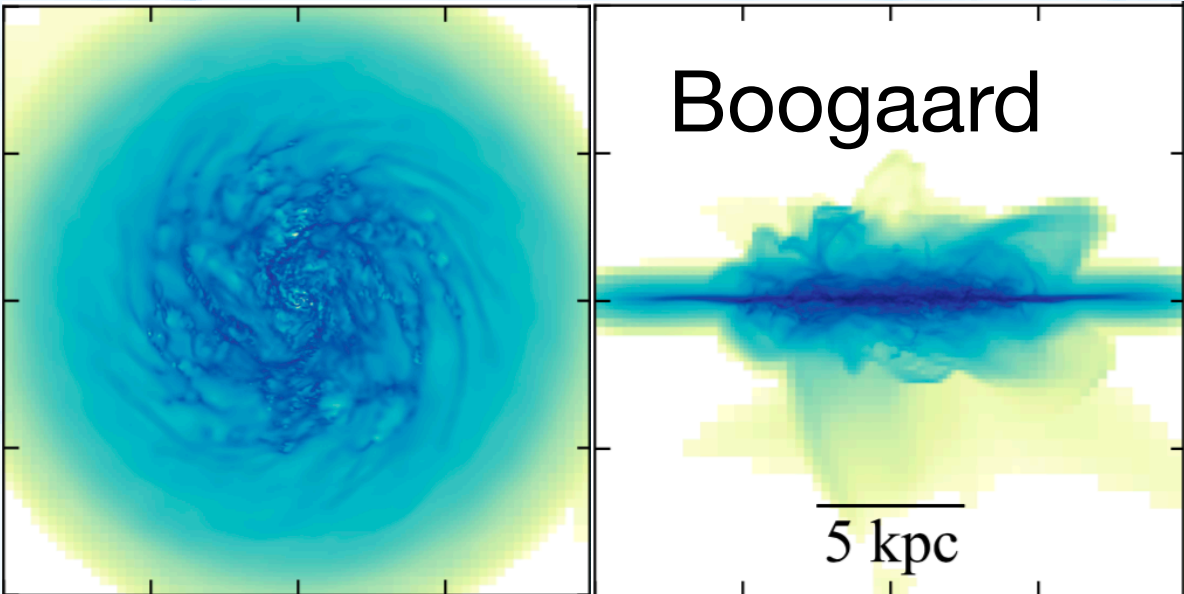

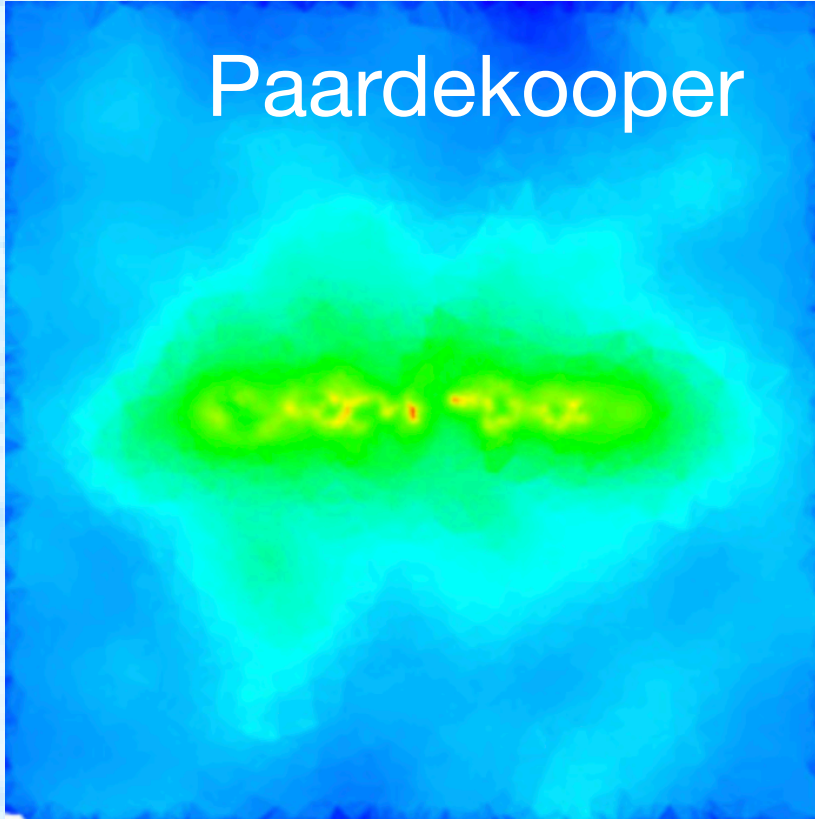

$\Delta x > 40 \text{ pc}$

**Low escape fractions !**

Similar results were found in other simulation works at the time, e.g. Razoumov & Sommer-Larsen (2006)

# $f_{esc}$ all over the place!

- Low  $f_{esc}$ :**
- Gnedin+07
  - Razoumov & Sommer-Larsen 06
  - Paardekooper+11
  - Ma+15
  - Boogaard+16

- High  $f_{esc}$ :**
- Wise&Cen 08
  - Yajima+11
  - Razoumov&Sommer-Larsen 10

**Feedback-regulated  $f_{esc}$**

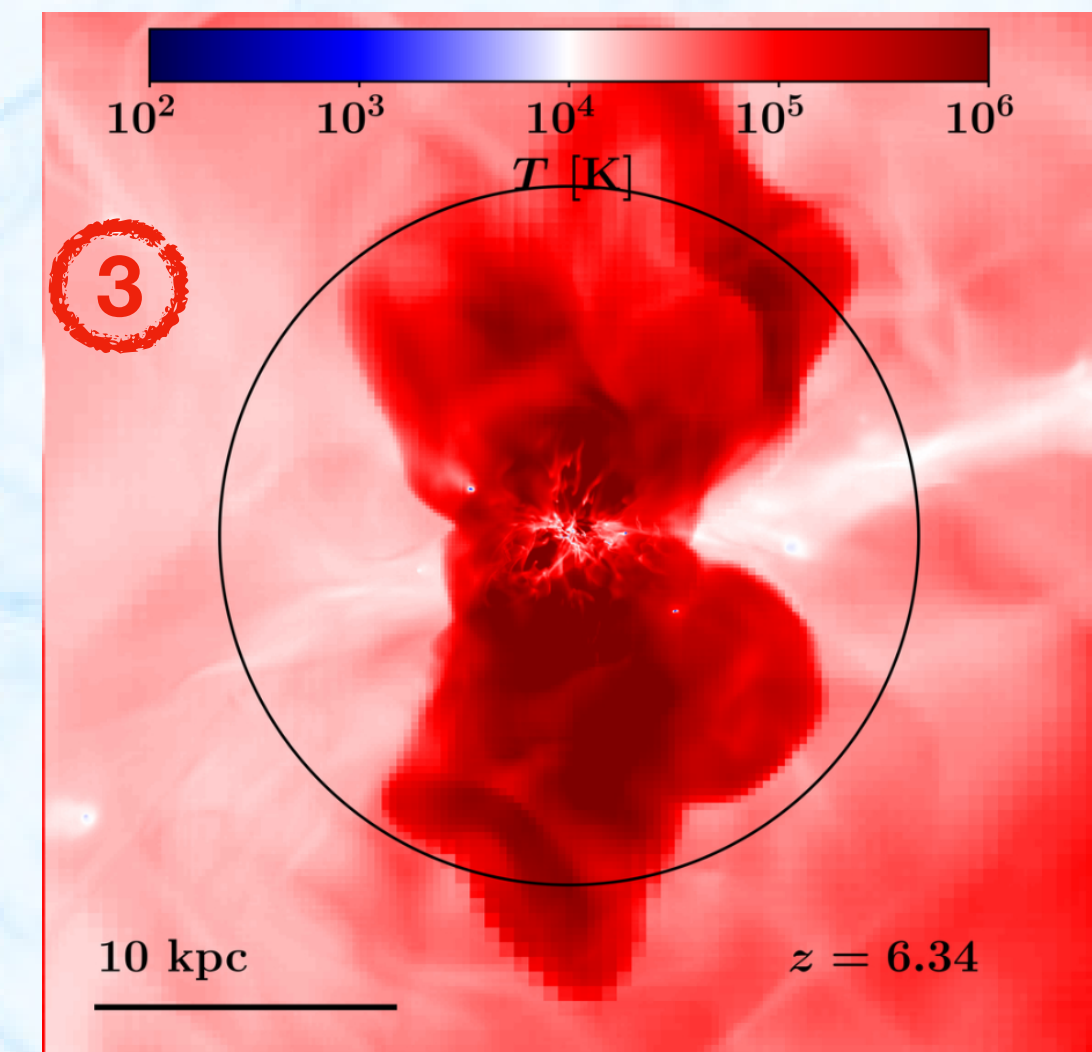

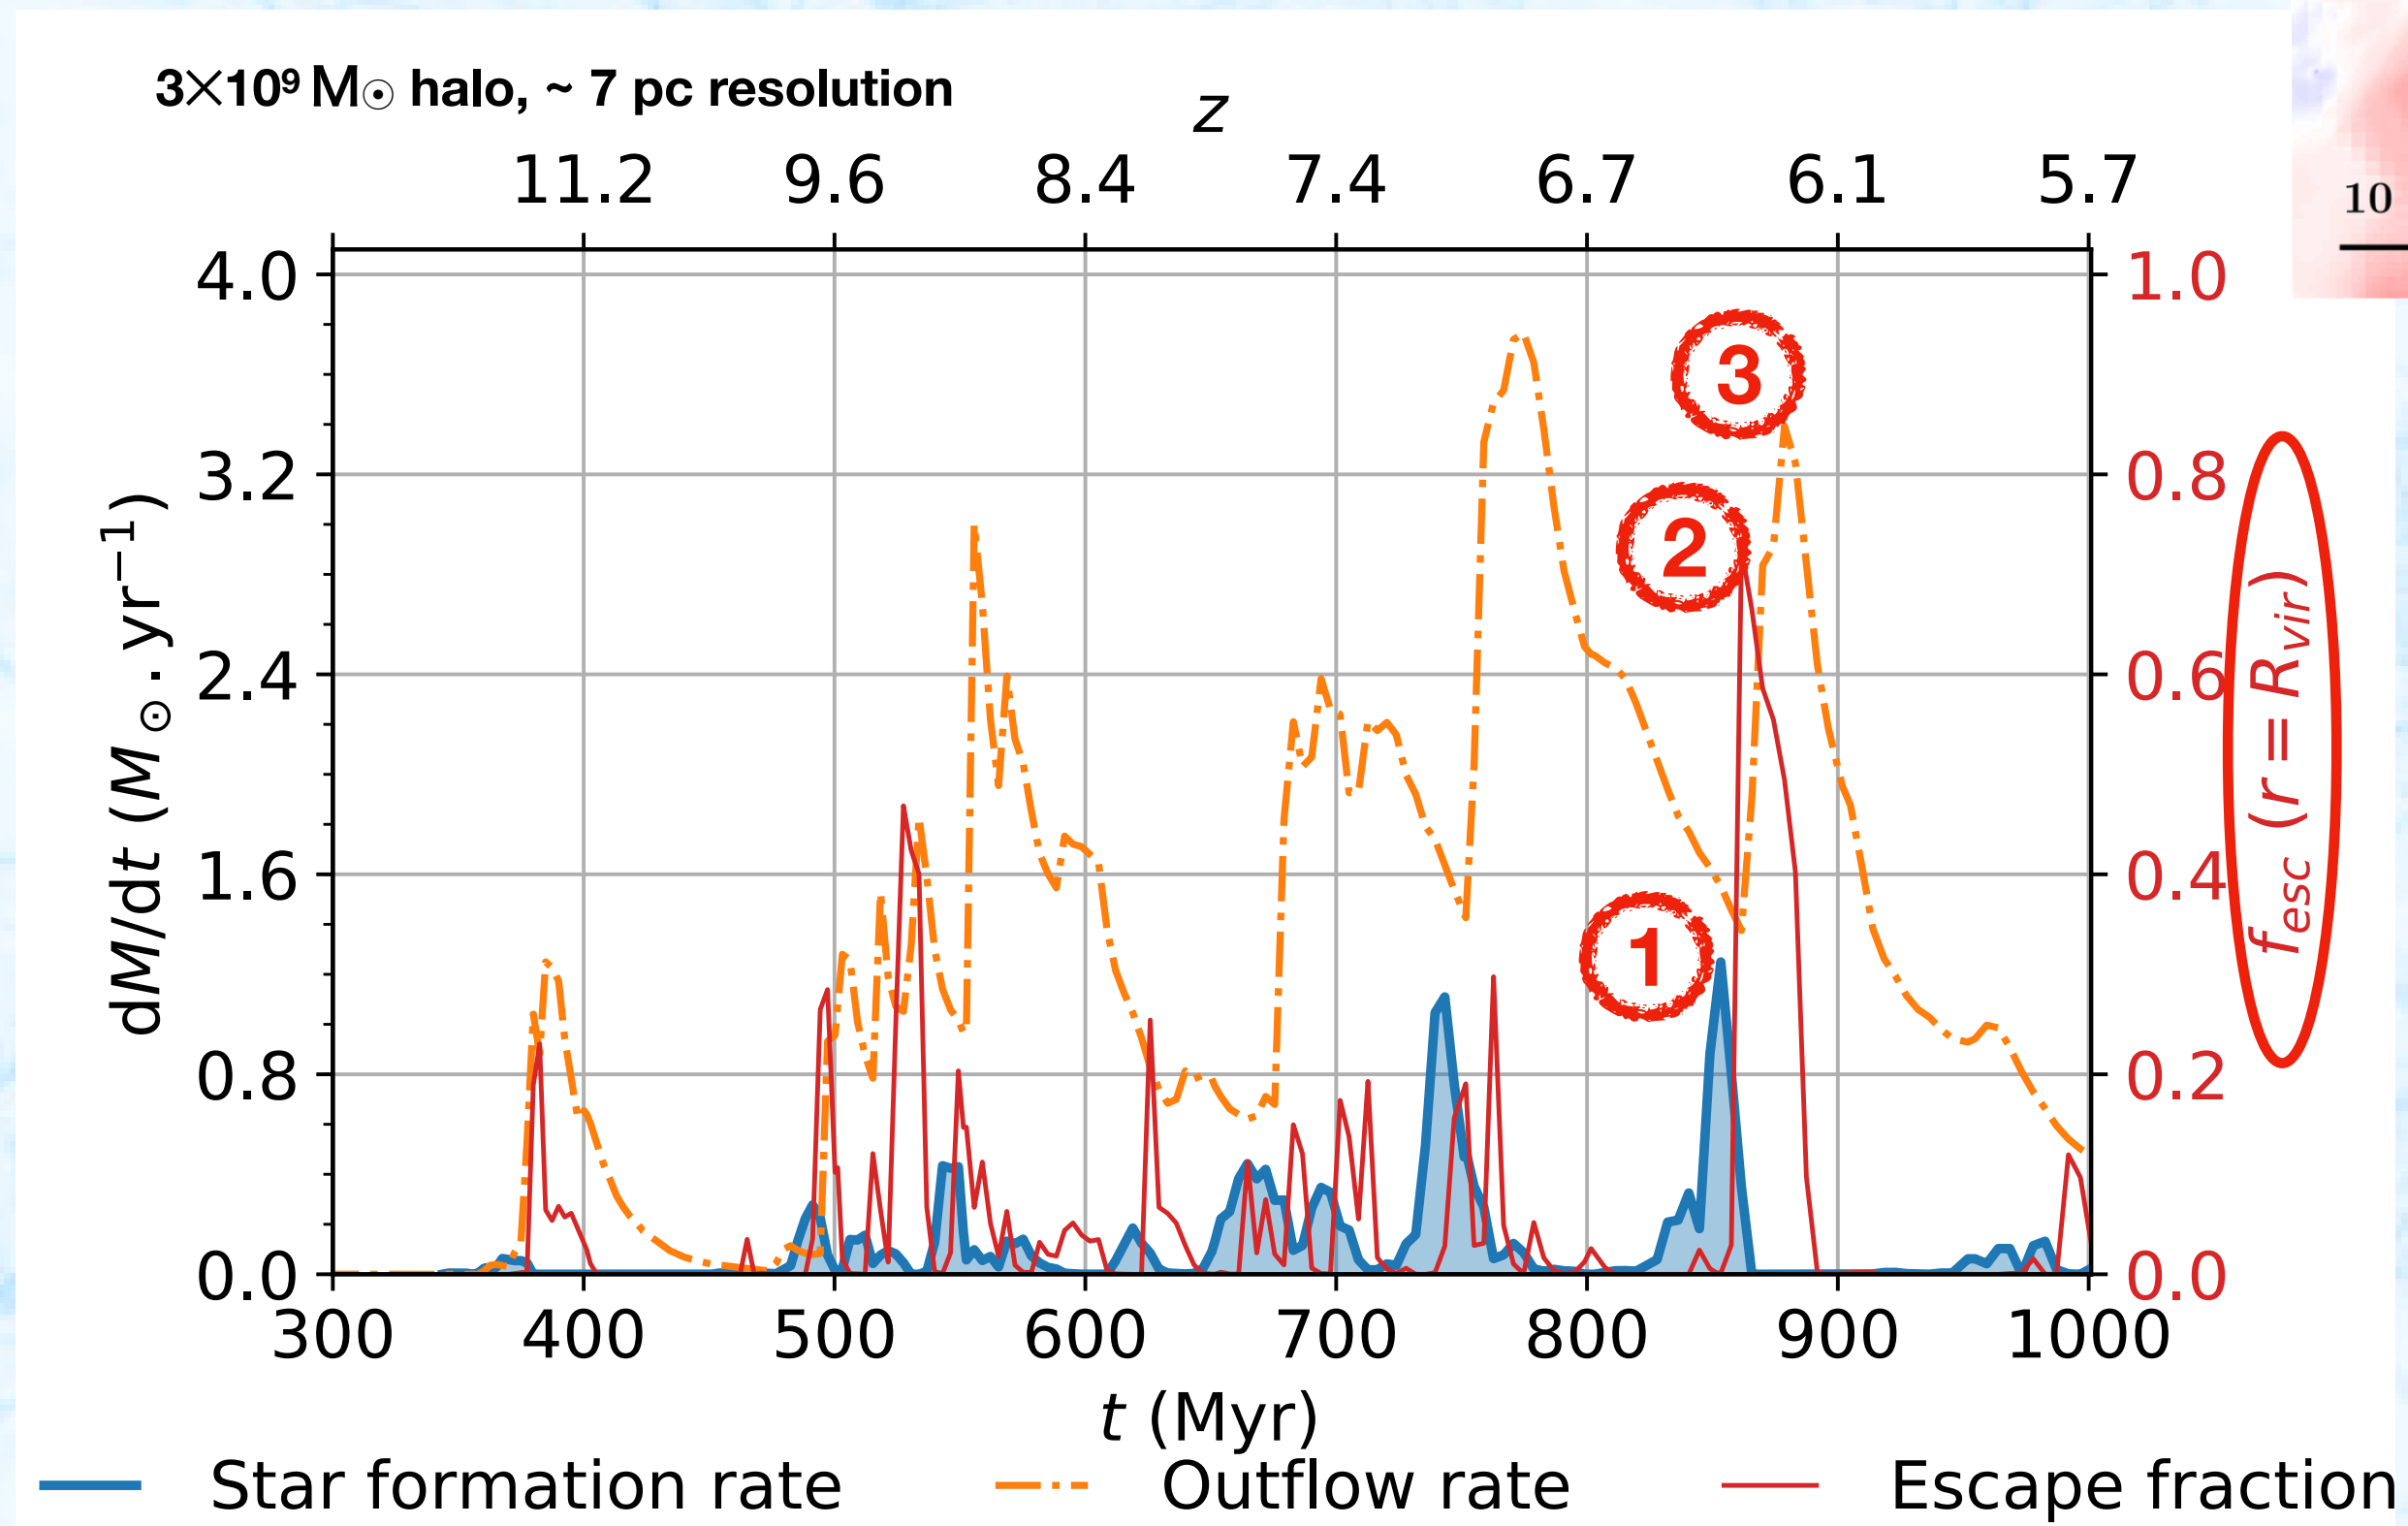

Kimm&Cen14, Wise+14, Paardekooper+15, Xu+16, Ma+15, Trebitsch+17

# Fluctuating **feedback-regulated** escape fraction of ionizing radiation in low-mass, high-redshift galaxies (2017)

Maxime Trebitsch<sup>1,2\*</sup>, J r my Blaizot<sup>2</sup>, Joakim Rosdahl<sup>2,3</sup>, Julien Devriendt<sup>2,4</sup> and Adrienne Slyz<sup>4</sup>

Study of  $f_{\text{esc}}$  from 3 high- $z$  halos with 7 pc resolution

➔  $f_{\text{esc}}$  is highly variable and SN-regulated

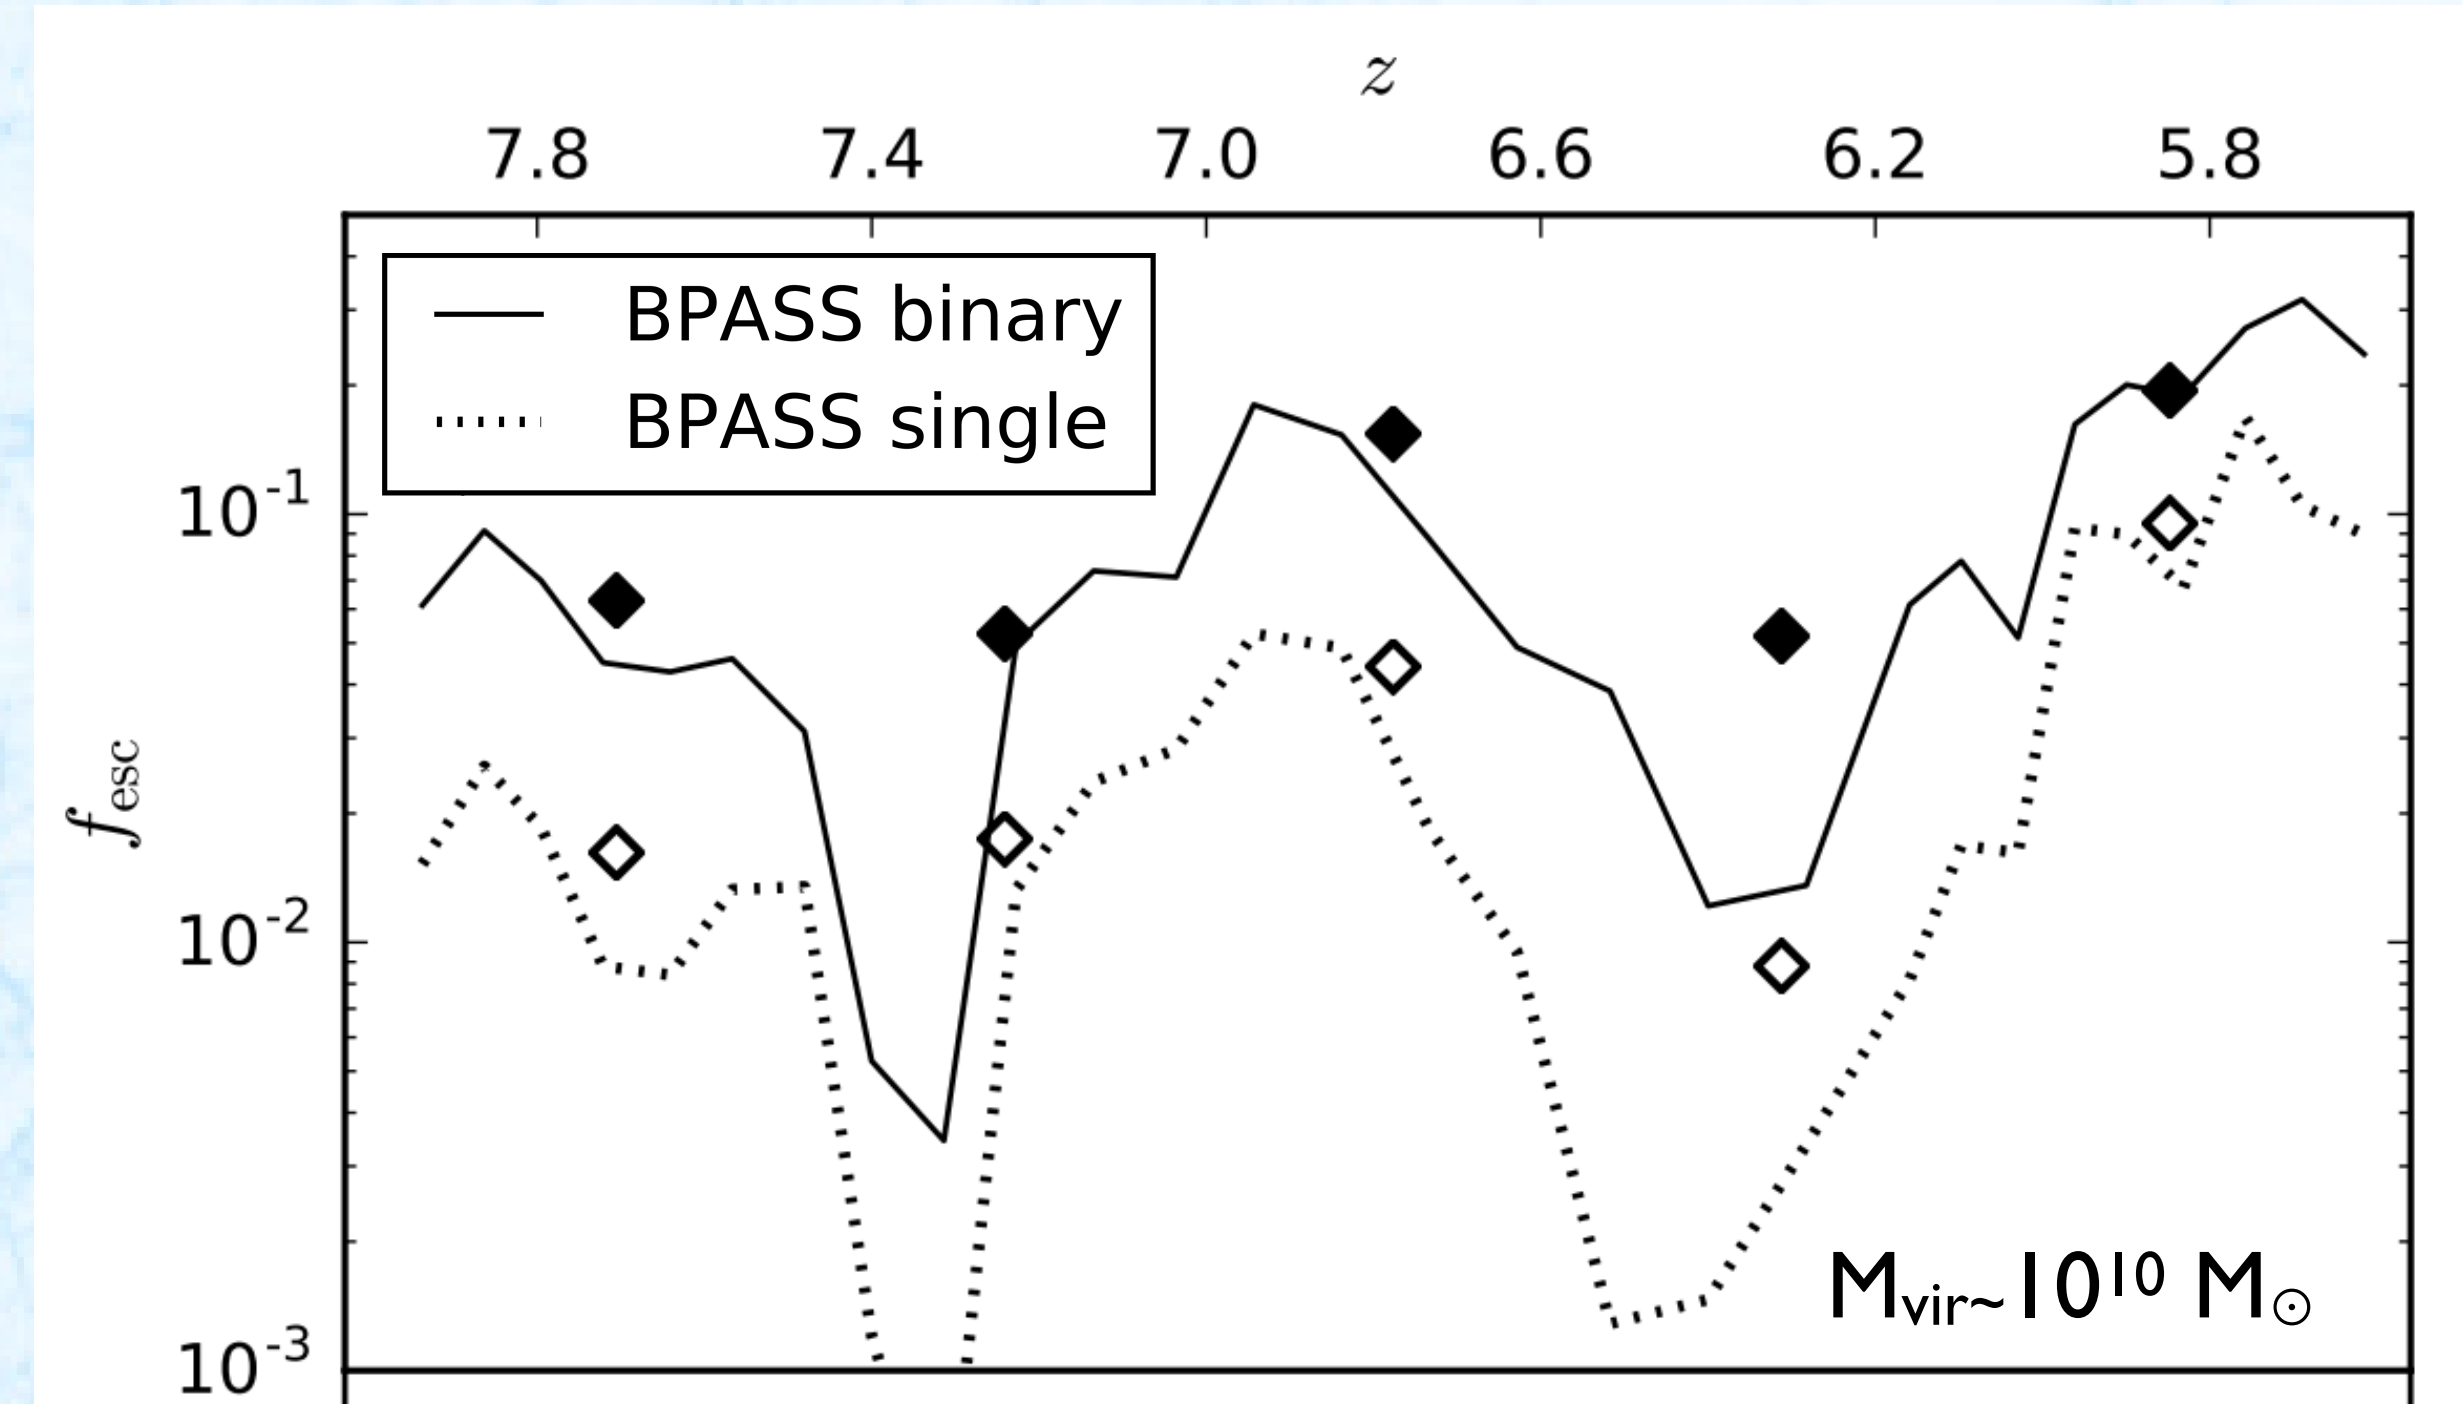

# Coupling feedback to stellar evolution

## Binary Stars Can Provide the “Missing Photons” Needed for Reionization (2016)

Xiangcheng Ma,<sup>1\*</sup> Philip F. Hopkins,<sup>1</sup> Daniel Kasen,<sup>2,3</sup> Eliot Quataert,<sup>2</sup> Claude-André Faucher-Giguère,<sup>4</sup> Dušan Kereš<sup>5</sup> Norman Murray<sup>6†</sup> and Allison Strom<sup>7</sup>

- Post-processing of cosmological zoom simulations, tracing rays from stellar sources, using binary and single SEDs

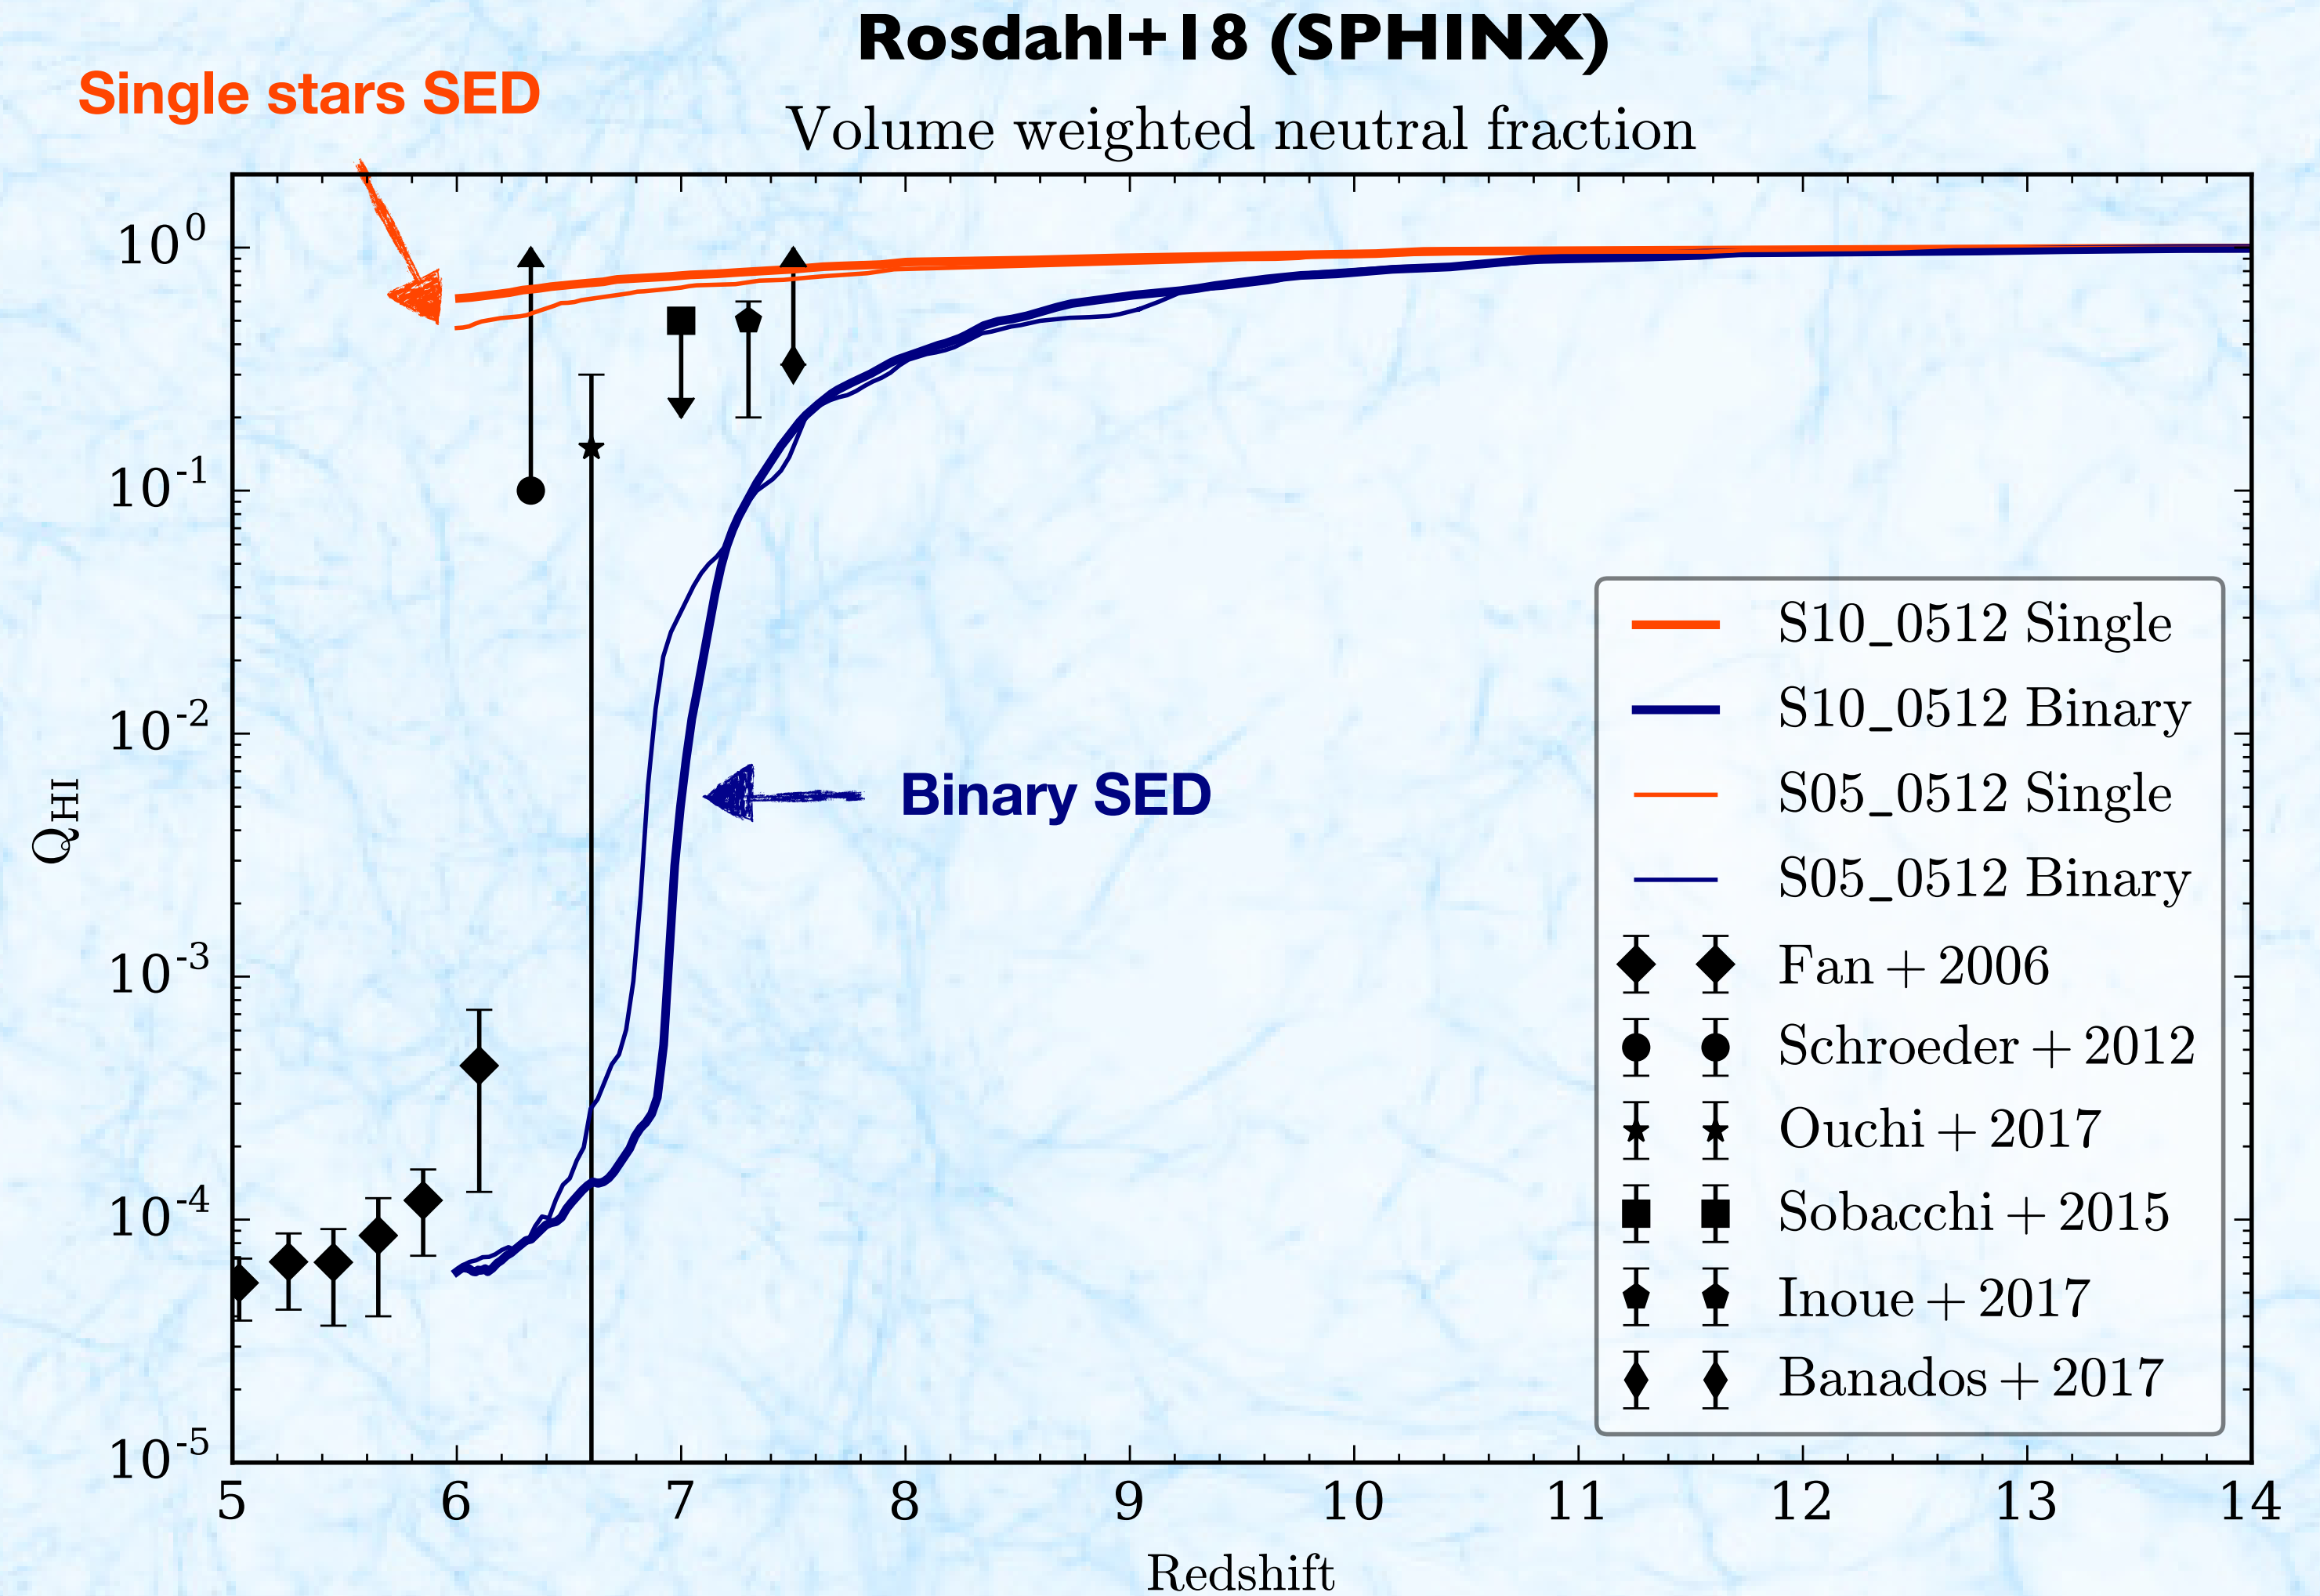

- Factor-few boost in  $f_{\text{esc}}$  with binaries !

# Coupling feedback to stellar evolution

This difference in escape fractions (and hence reionization history) is due to late time ( $\geq 5$  Myr) boost in LyC luminosities of binary stars with exposed helium cores

# Radiation-Feedback-regulated star formation and escape of LyC photons from **mini-haloes** during reionisation (2017)

Taysun Kimm<sup>1\*</sup>, Harley Katz<sup>1</sup>, Martin Haehnelt<sup>1</sup>, Joakim Rosdahl<sup>2</sup>, Julien Devriendt<sup>3,4</sup>,  
Adrienne Slyz<sup>3</sup>

'Zoomed' 2 cMpc wide volume, **0.7 pc resolution**, allowing for resolved HII regions

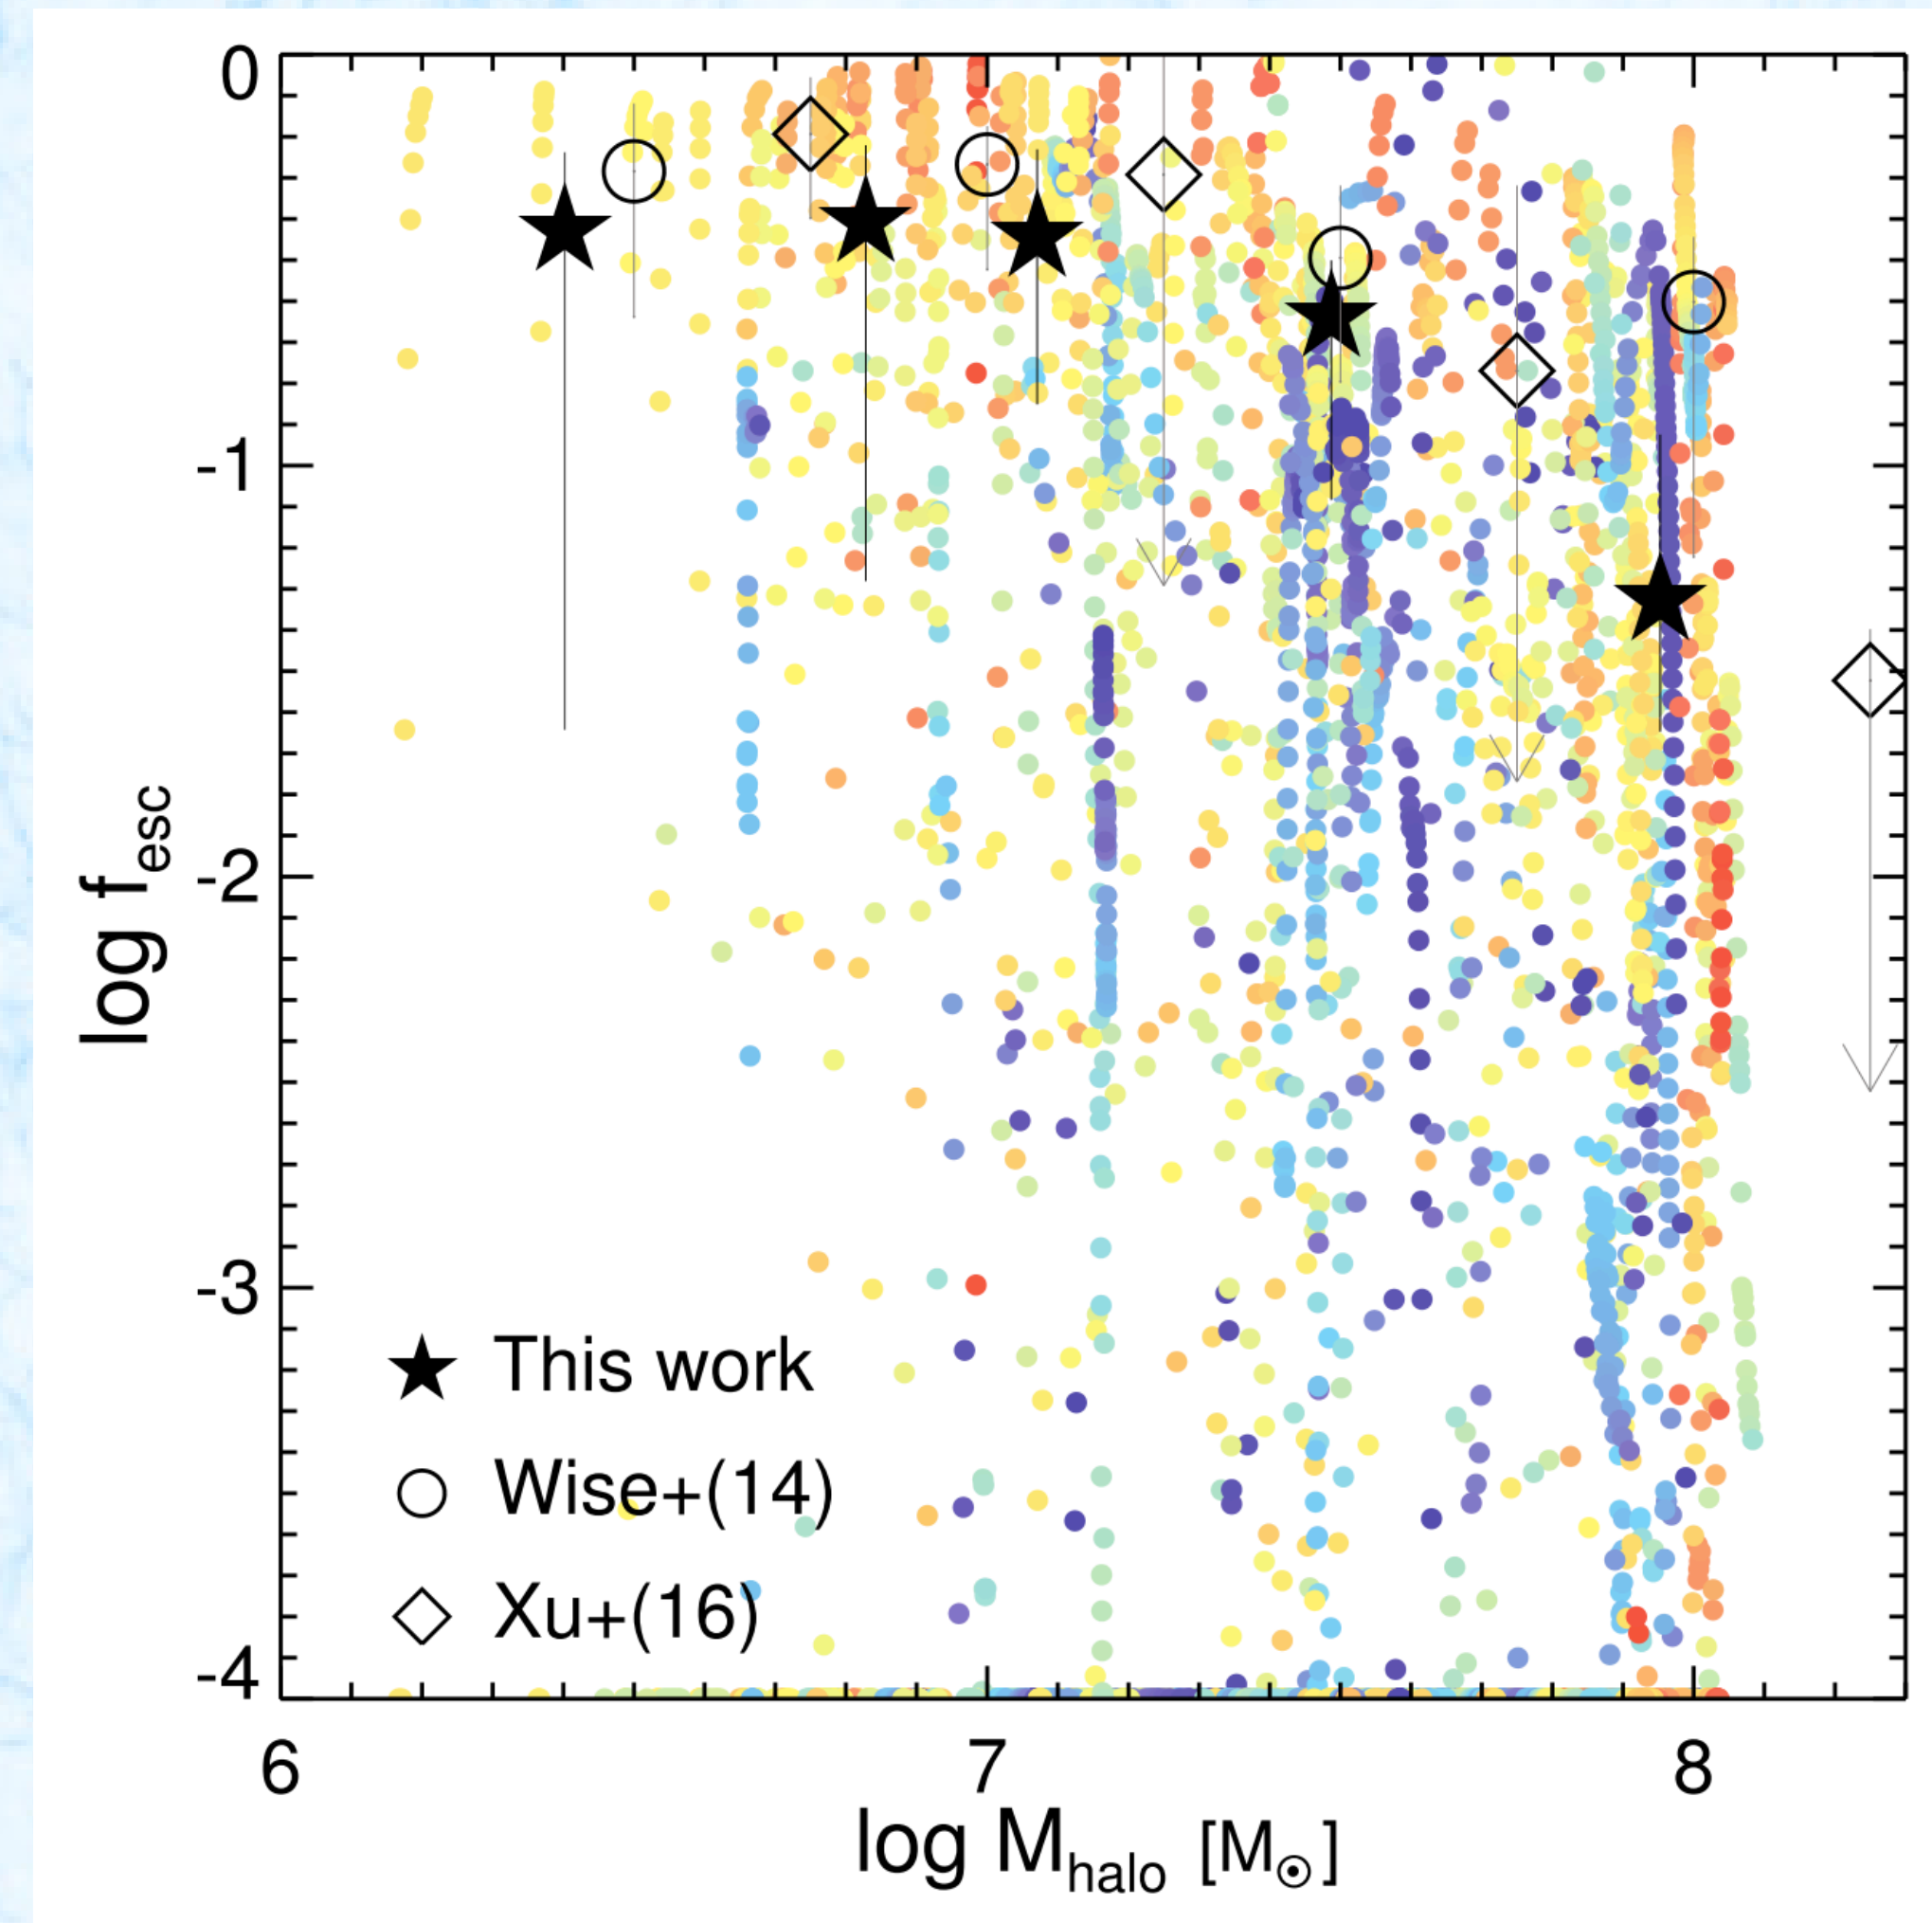

# Feedback-regulated star formation and escape of LyC photons from mini-haloes during reionisation (2017)

Taysun Kimm<sup>1\*</sup>, Harley Katz<sup>1</sup>, Martin Haehnelt<sup>1</sup>, Joakim Rosdahl<sup>2</sup>, Julien Devriendt<sup>3,4</sup>,  
Adrianne Slyz<sup>3</sup>

‘Zoomed’ 2 cMpc wide volume, 0.7 pc resolution (in a small part of the volume)

- Mini-halos have high  $f_{\text{esc}}$ ,
- but these galaxies shut themselves down with their own radiation,
- so not much contribution to reionization.

**Towards newer and larger simulations**

**How do LyC escape fractions correlate with galaxy properties?**

**What do simulations find, and do they agree?**

# The Key Players

(From Garaldi et al. 2024)

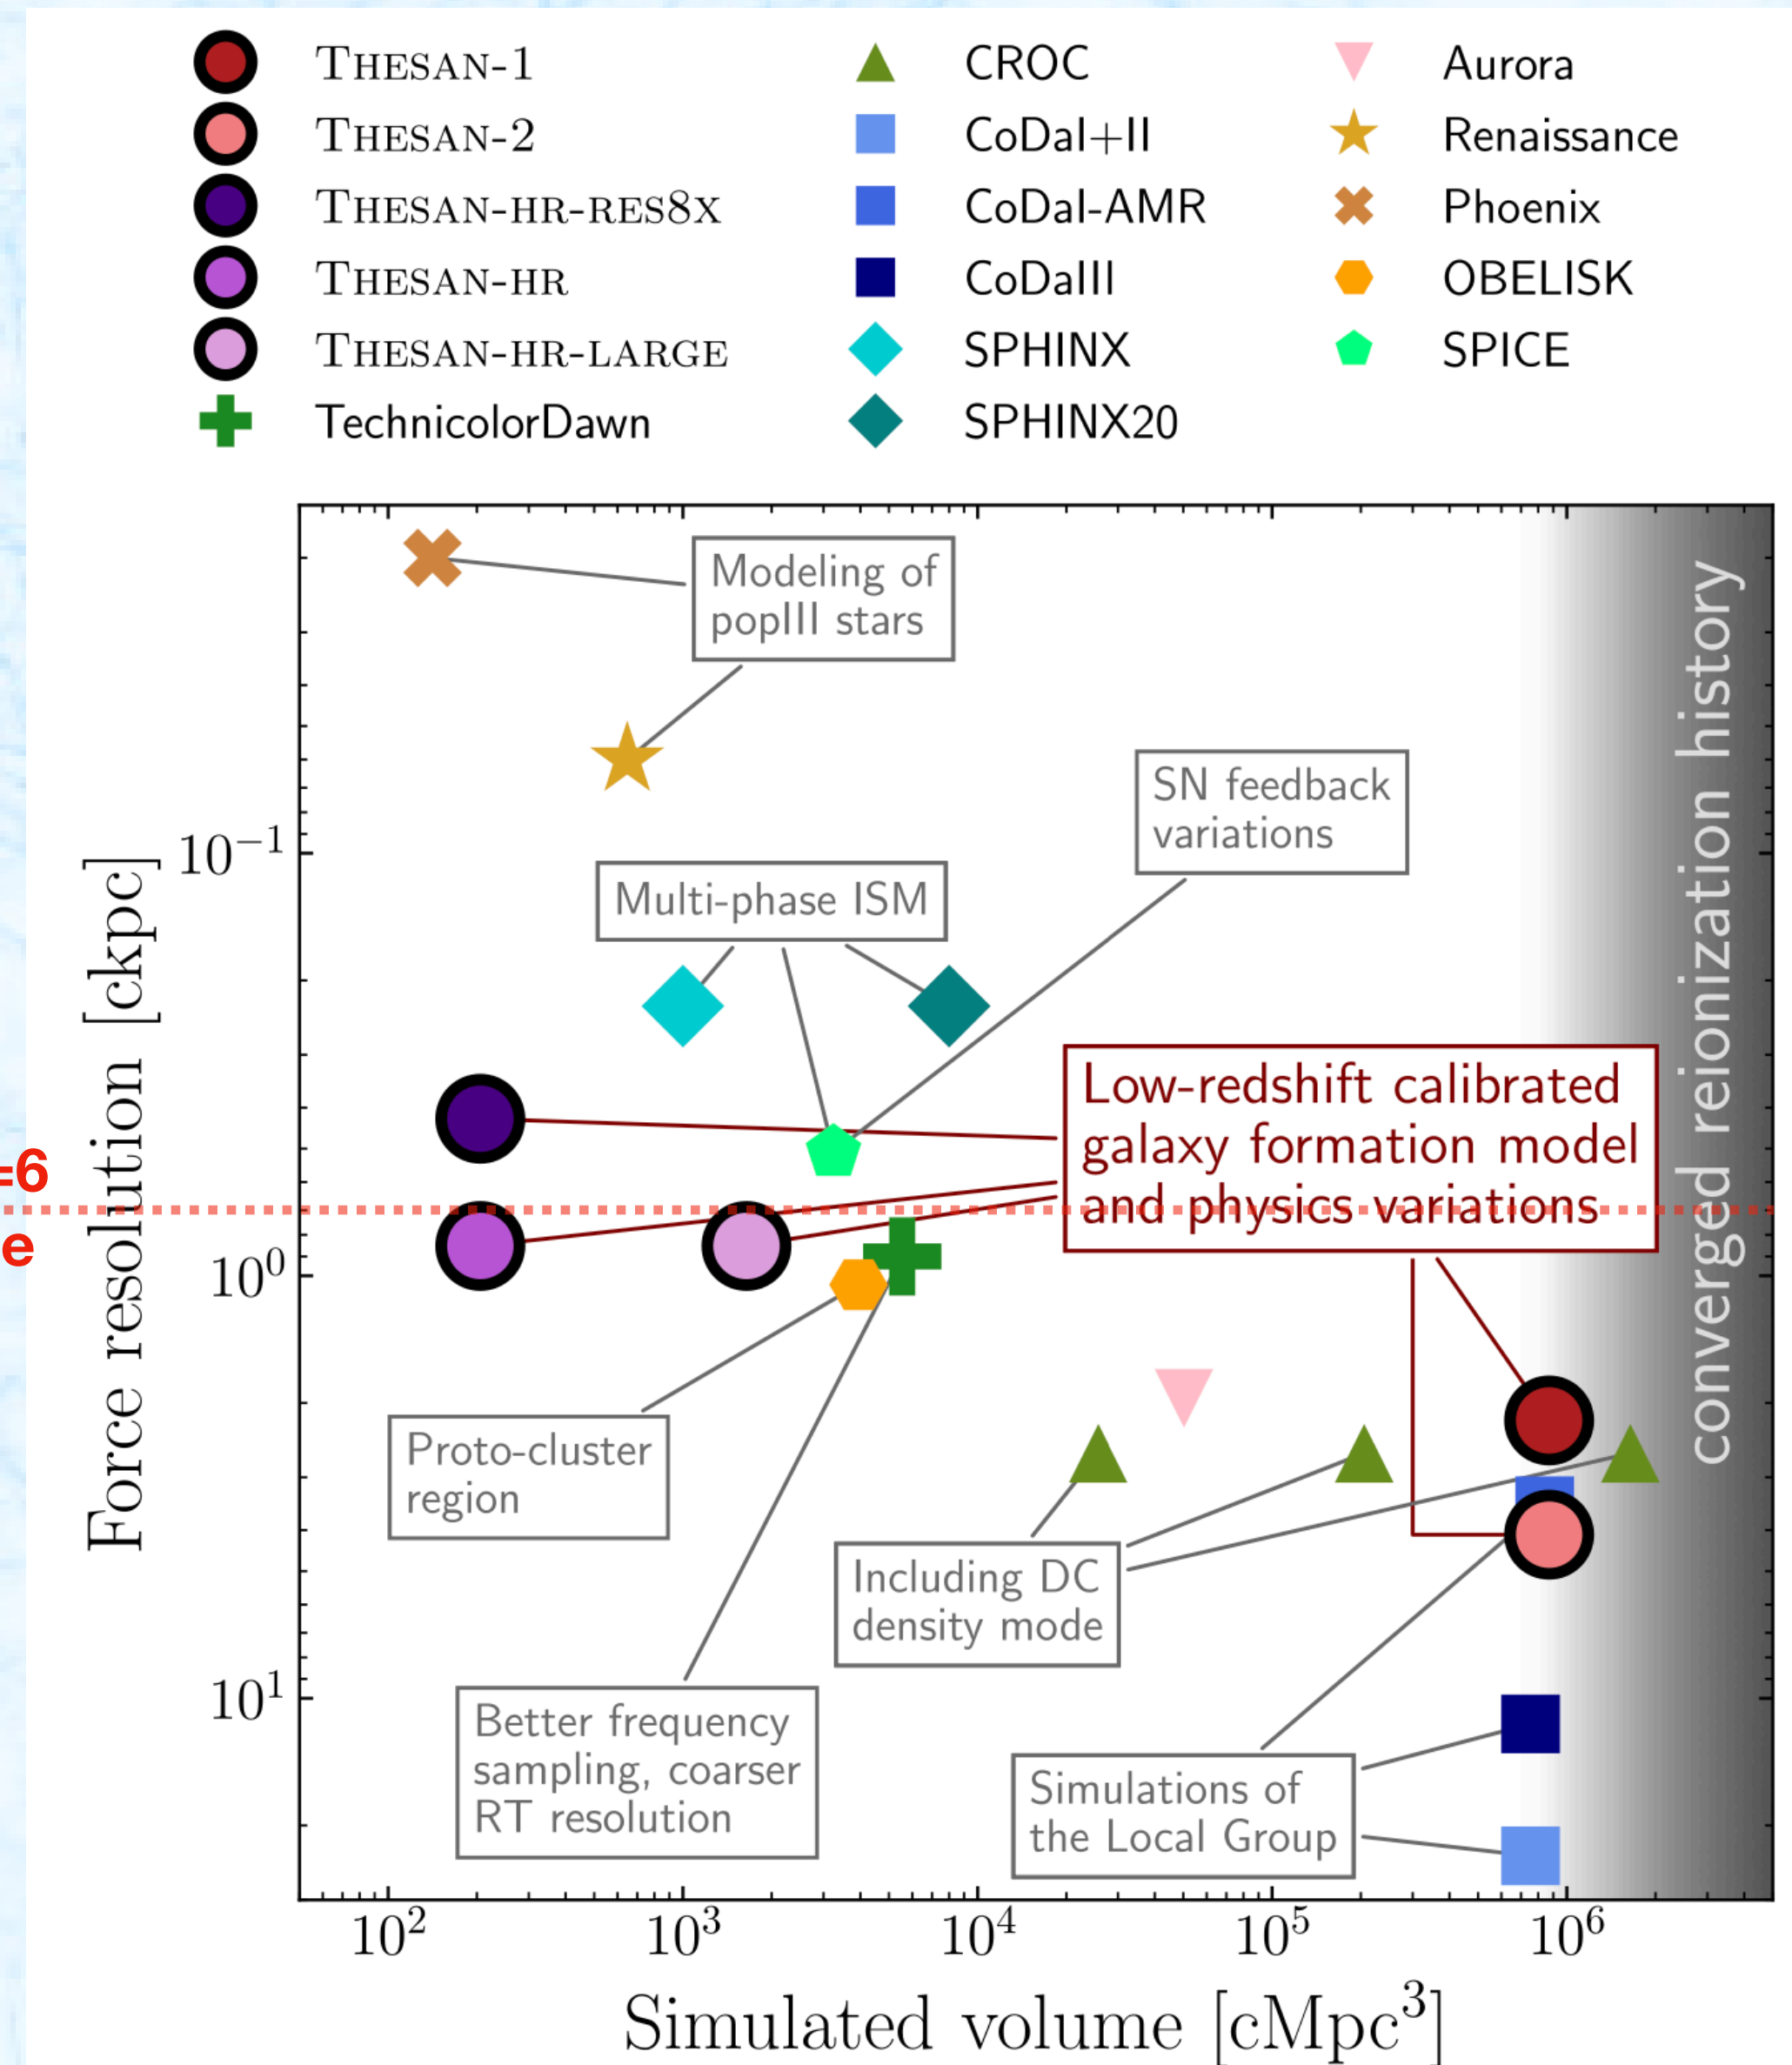

Strong trade-off between resolution and statistics — and we need both!

This is restricted to cosmological radiation-hydrodynamical simulations

Other non-RHD cosmological simulations are used to probe correlations of  $f_{\text{esc}}$  with galaxy properties, e.g.:

- FiBy (Paardekooper+15)
- FIRE (Ma+16,20)
- IllustrisTNG (Kostyuk+24)

100 pc at  $z=6$   
(size of large SF clouds)

# $\langle f_{\text{esc}} \rangle$ vs halo mass

Paardekooper+I5 (FiBy, pure hydro cosmo-sim)

Decrease of mean  $f_{\text{esc}}$  with halo mass, for  $M_{\text{halo}} \gtrsim 10^8 M_{\odot}$

(and a lot of noise)

# $f_{esc}$ vs halo mass

Xu+16 (Renaissance)

Decrease with halo mass, for  $M_{halo} \gtrsim 10^8 M_{\odot}$

# $\langle f_{\text{esc}} \rangle$ vs halo mass

Ma+20 (FIRE, pure hydro cosmo-zooms)

Decrease of  $L_{\text{LyC}}$ -weighted  $f_{\text{esc}}$  with halo mass, for  $M_{\text{halo}} \gtrsim 10^{11} M_{\odot}$ , depending on resolution

Very strong feedback in FIRE

# $\langle f_{\text{esc}} \rangle$ vs halo mass

Lewis+22 (CoDa cosmological RHD simulation)

Decrease of  $\langle f_{\text{esc}} \rangle$  with halo mass,  
for  $M_{\text{halo}} \gtrsim 10^9 M_{\odot}$

$$f_{\text{net}}^{\text{esc}} = 0.42 f_{\text{ray}}^{\text{esc}}$$

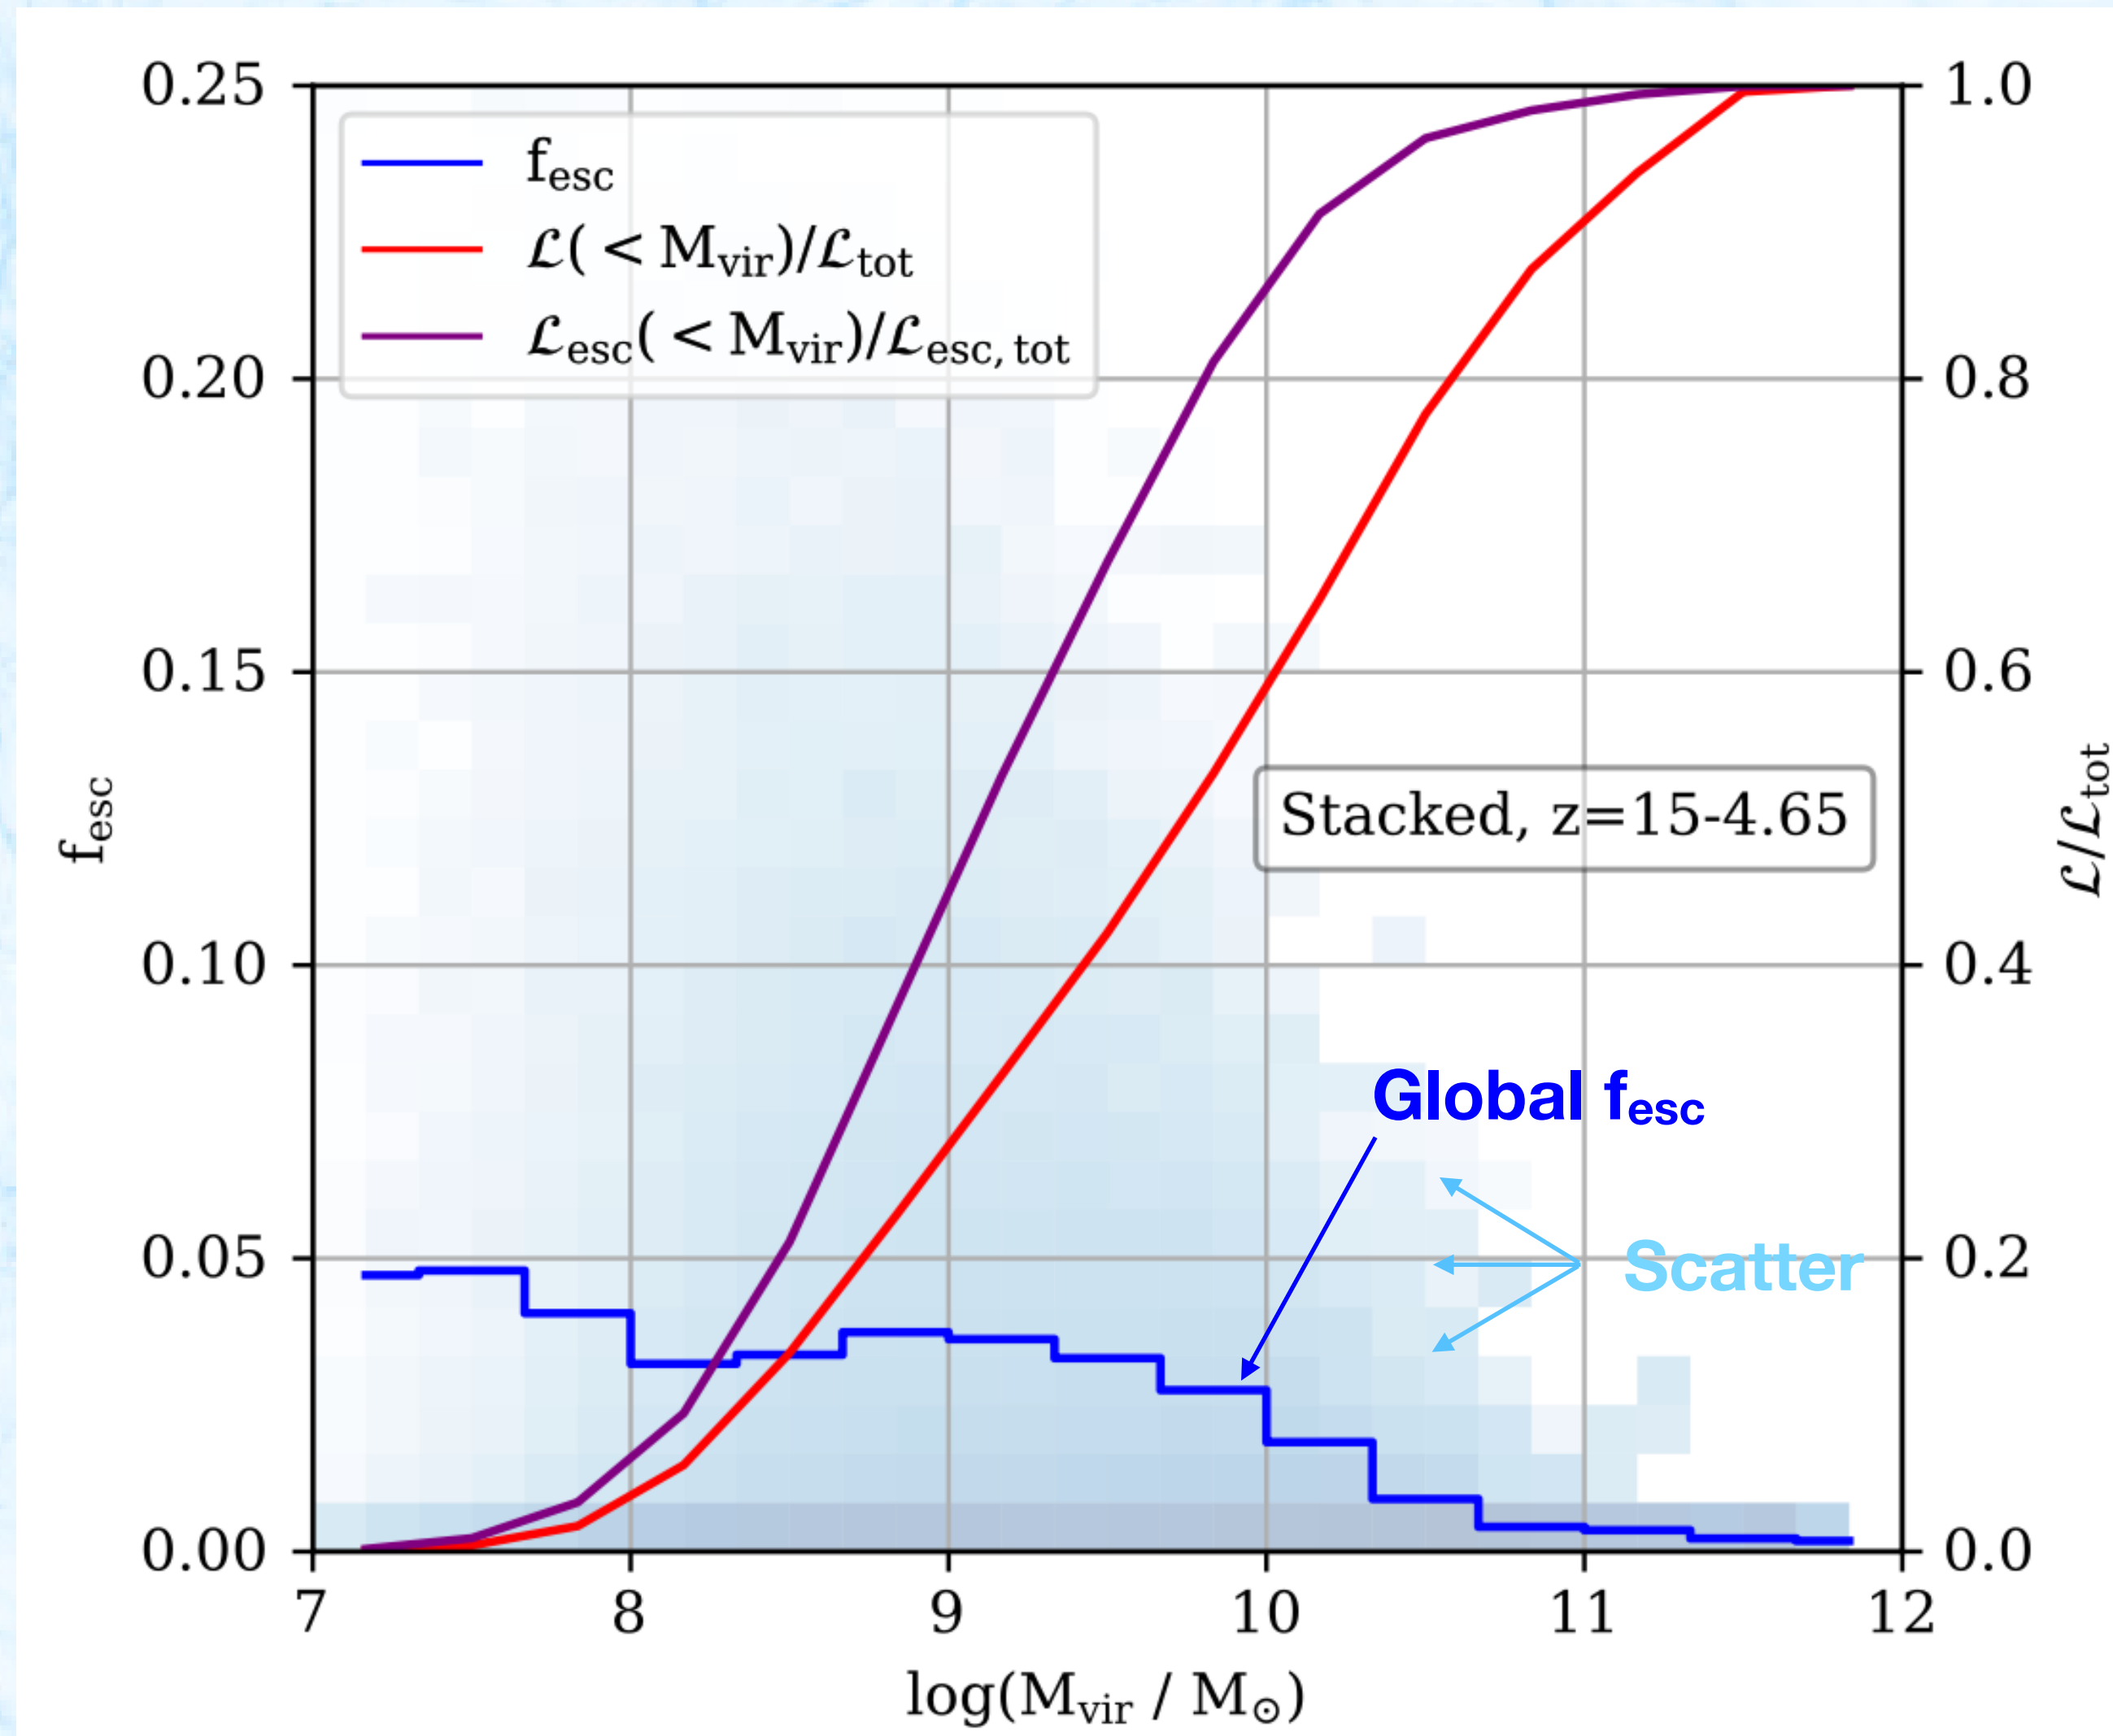

# $\langle f_{\text{esc}} \rangle$ vs halo mass

## Rosdahl+22 (SPHINX)

Decrease with halo mass,  
for  $M_{\text{halo}} \gtrsim 10^9 M_{\odot}$

Similar trend to CoDa, even if  
 $\sim 100$  times higher ISM  
resolution

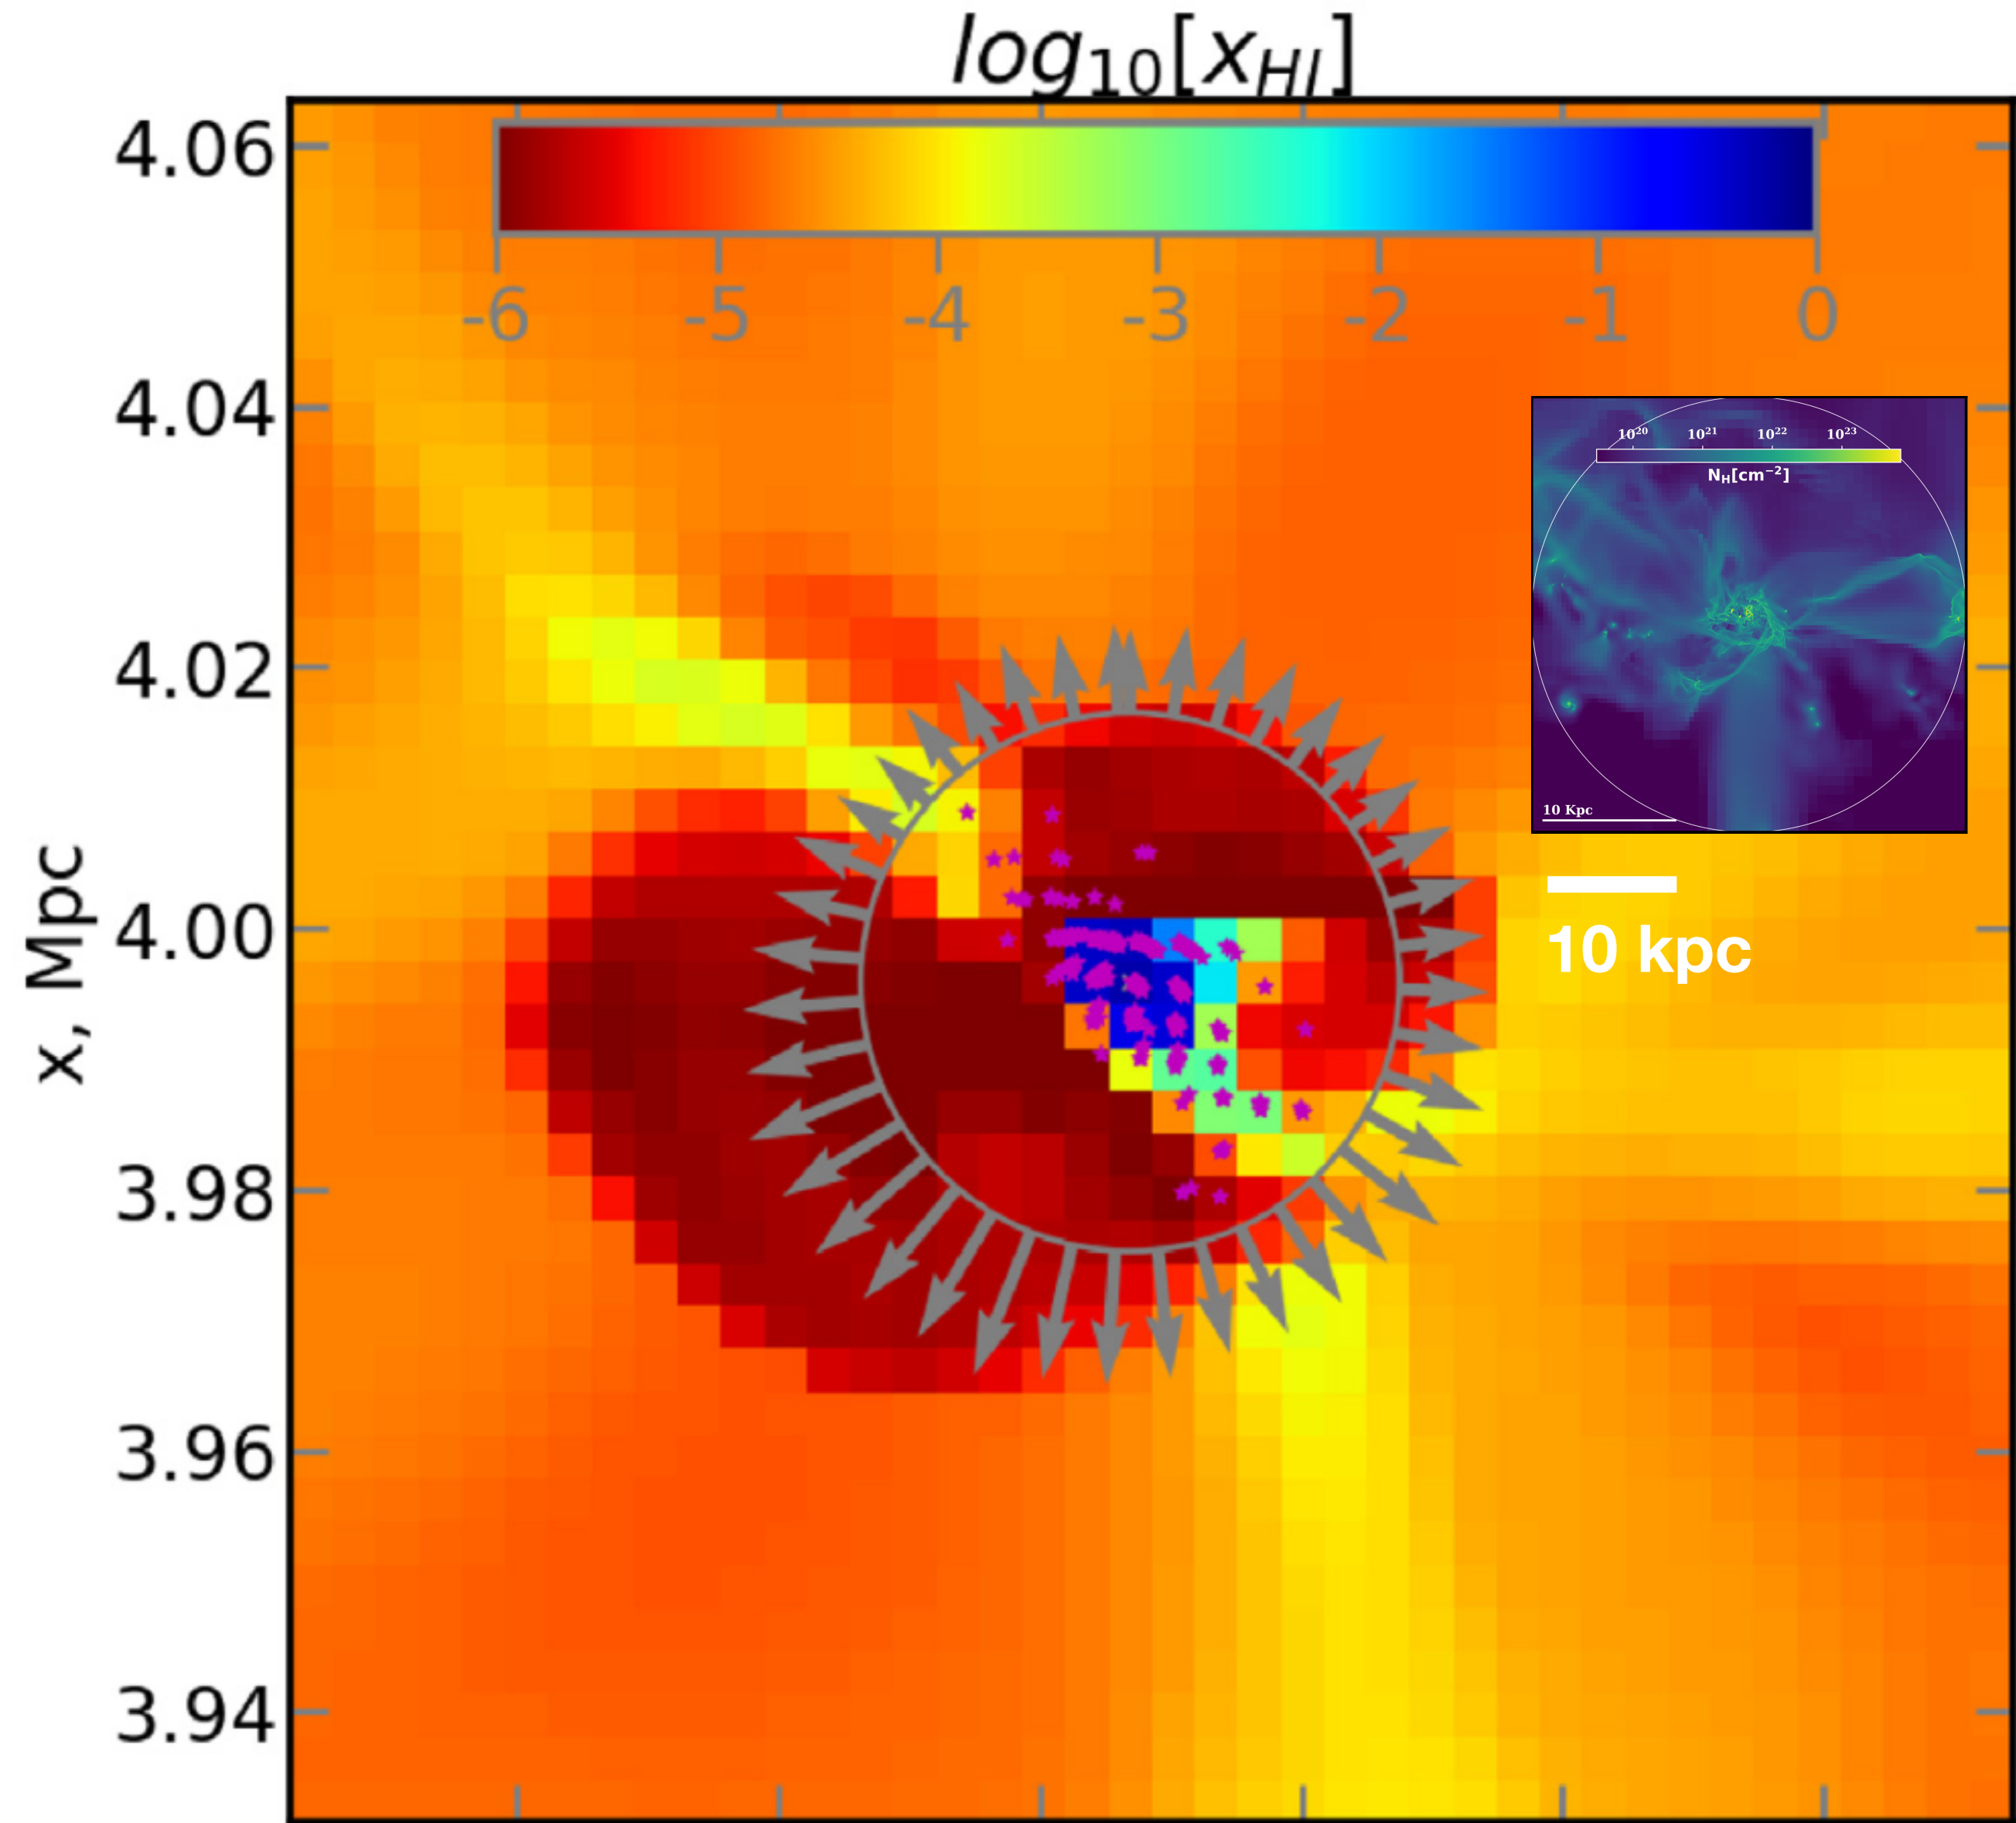

# $\langle f_{\text{esc}} \rangle$ vs halo mass

Rosdahl+22 (SPHINX)

Decrease with halo mass,  
for  $M_{\text{halo}} \gtrsim 10^9 M_{\odot}$

Similar trend to CoDa, even if  
 $\sim 100$  times higher ISM  
resolution

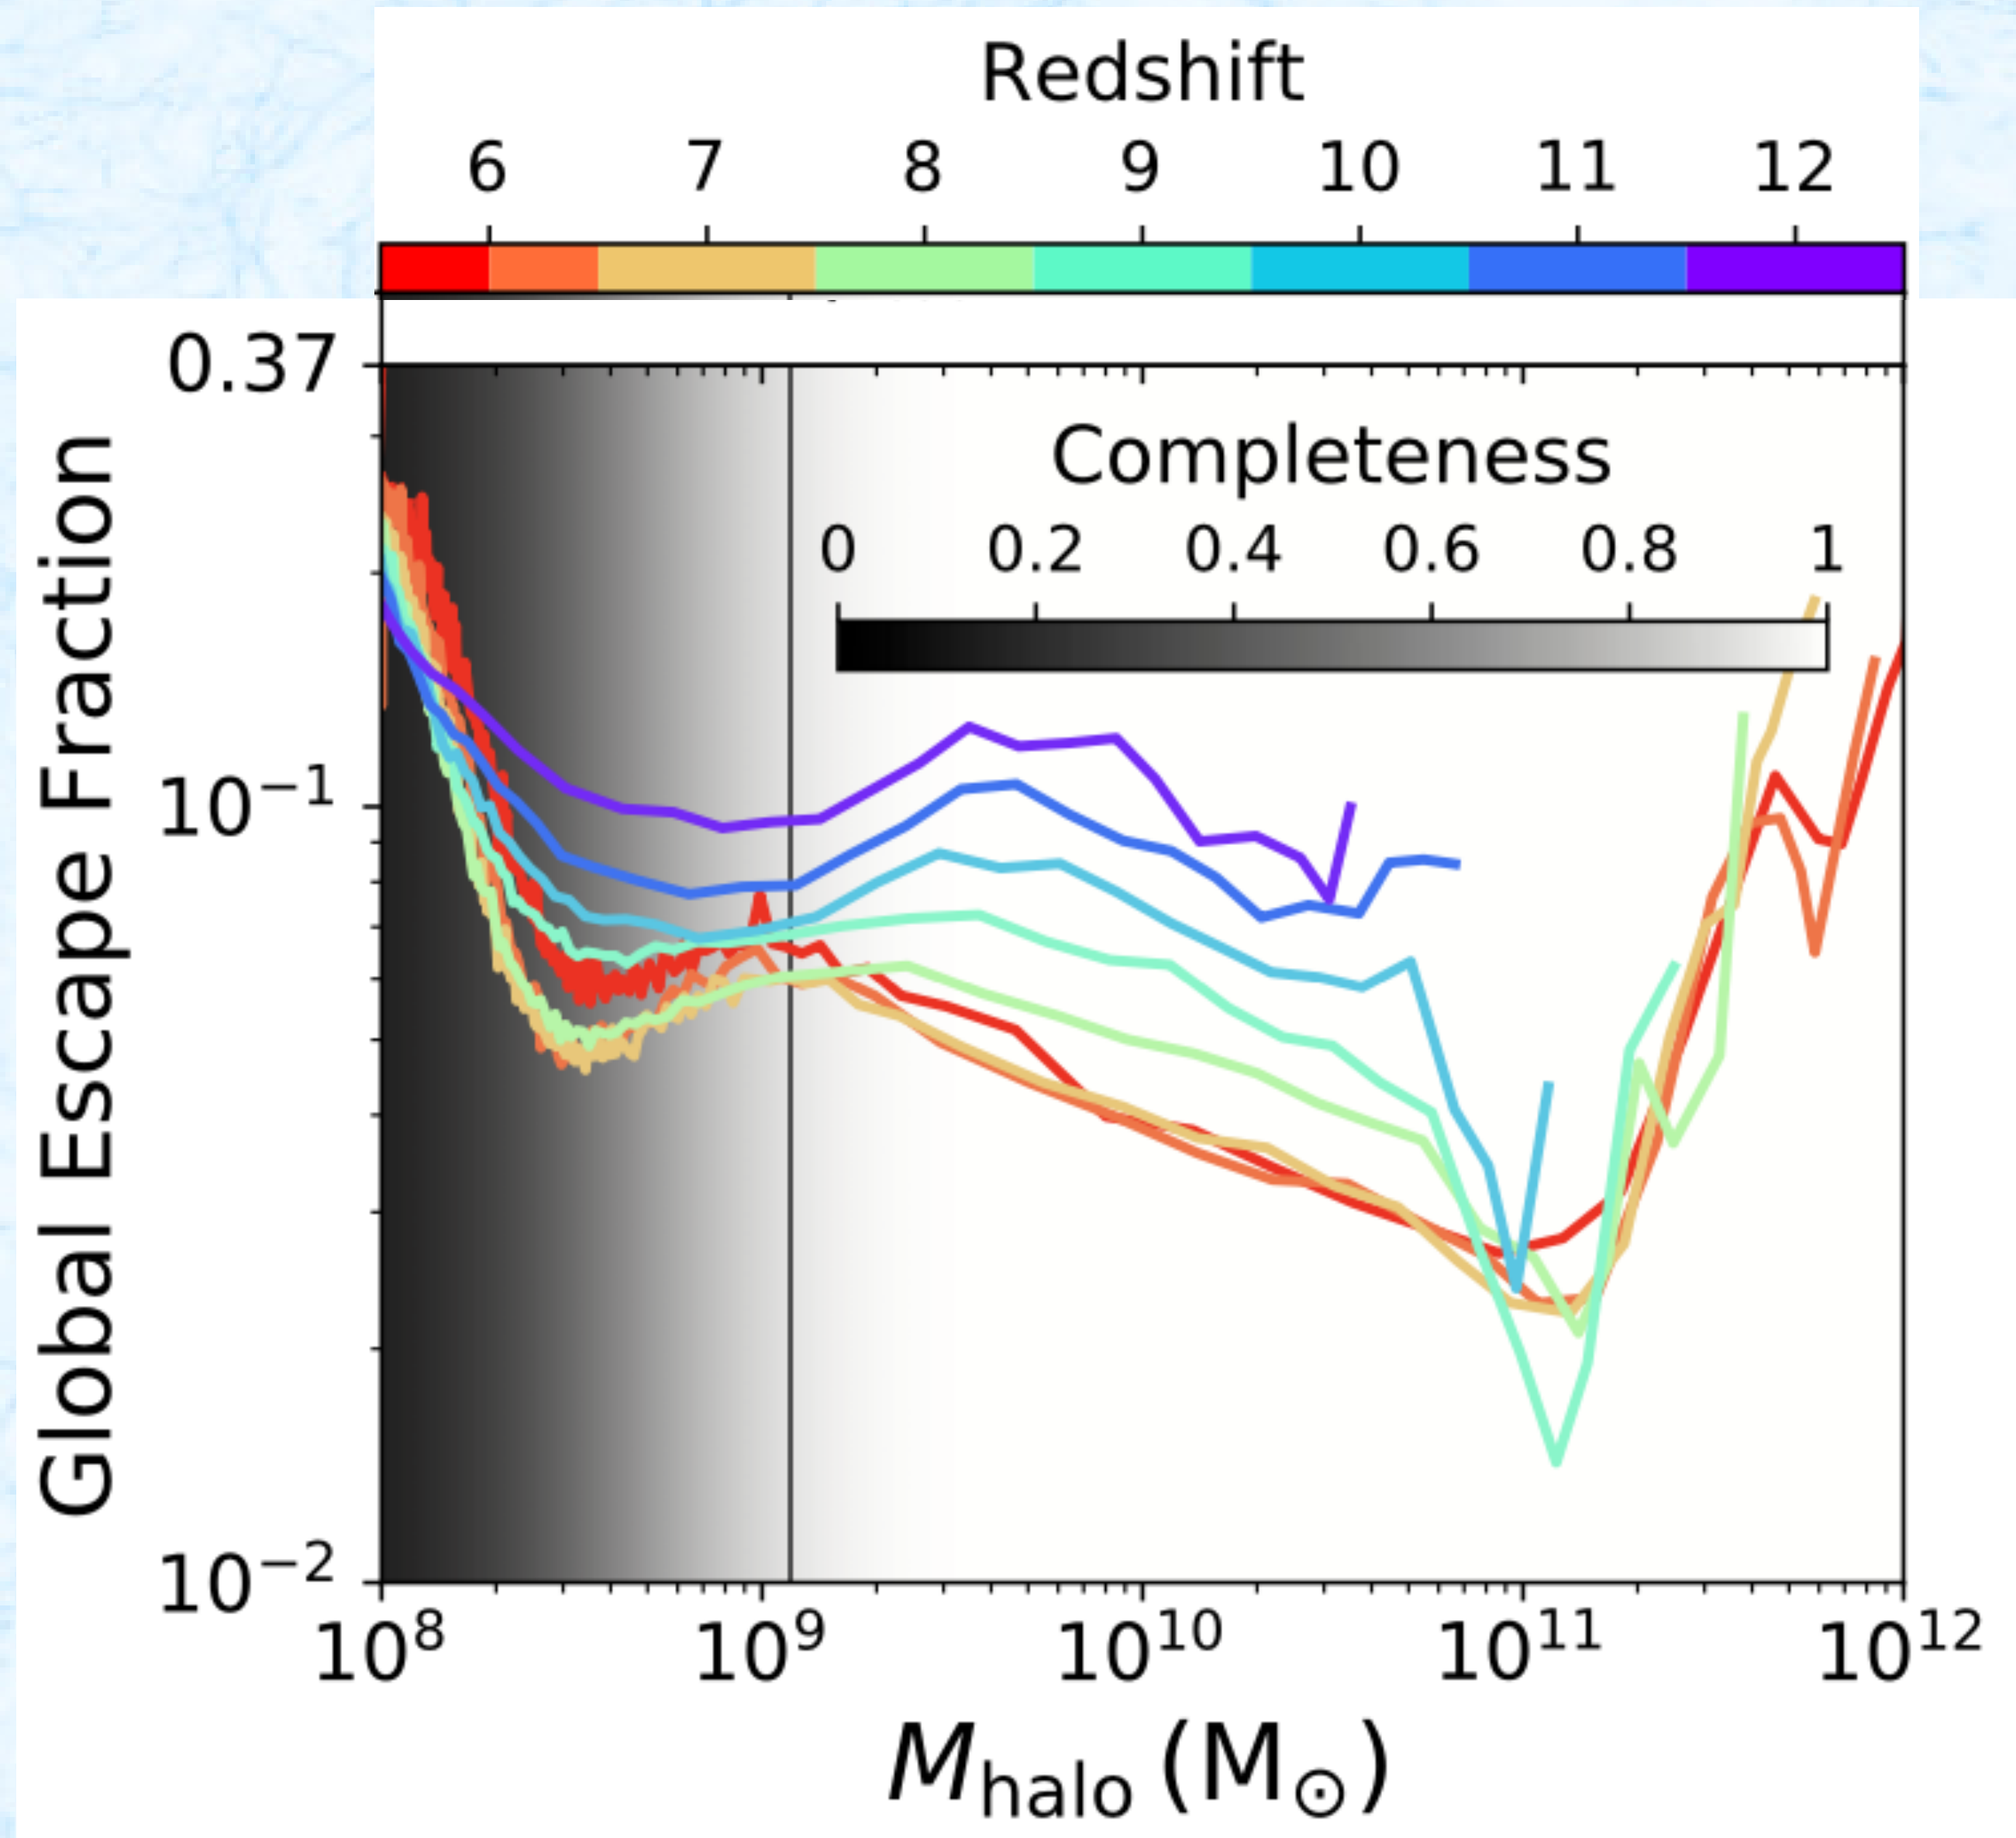

# $\langle f_{\text{esc}} \rangle$ vs halo mass

Yeh+22 (THESAN)

Usual trend for global  $f_{\text{esc}}$  at lower masses: decrease with halo mass for  $M_{\text{halo}} \sim 10^9 - 10^{11} M_{\odot}$

But sharp increase in massive halos.  
AGN or sub-grid feature?  
➡ we will know in THESAN-TNG

# $f_{\text{esc}}$ vs halo mass

Kostyuk+23 (IllustrisTNG)

What to make of this? 😬

Reasons for discrepancies:

- different definitions of  $\langle f_{\text{esc}} \rangle$
- different resolutions and **sub-grid models**

Yet same models in THESAN and TNG produces quite different  $f_{\text{esc}}$

CODA, THESAN, SPHINX all produce reasonable reionization histories, UV luminosity functions, and Thomson optical depths, due to large uncertainties in observations and trade-off between SFR and  $f_{\text{esc}}$

# $f_{\text{esc}}$ vs halo mass

Kostyuk+23 (IllustrisTNG)

What to make of this? 🤔

Reasons for discrepancies:

- different definitions of  $\langle f_{\text{esc}} \rangle$
- different resolutions and **sub-grid models**

Yet same models in THESAN and TNG produces quite different  $f_{\text{esc}}$

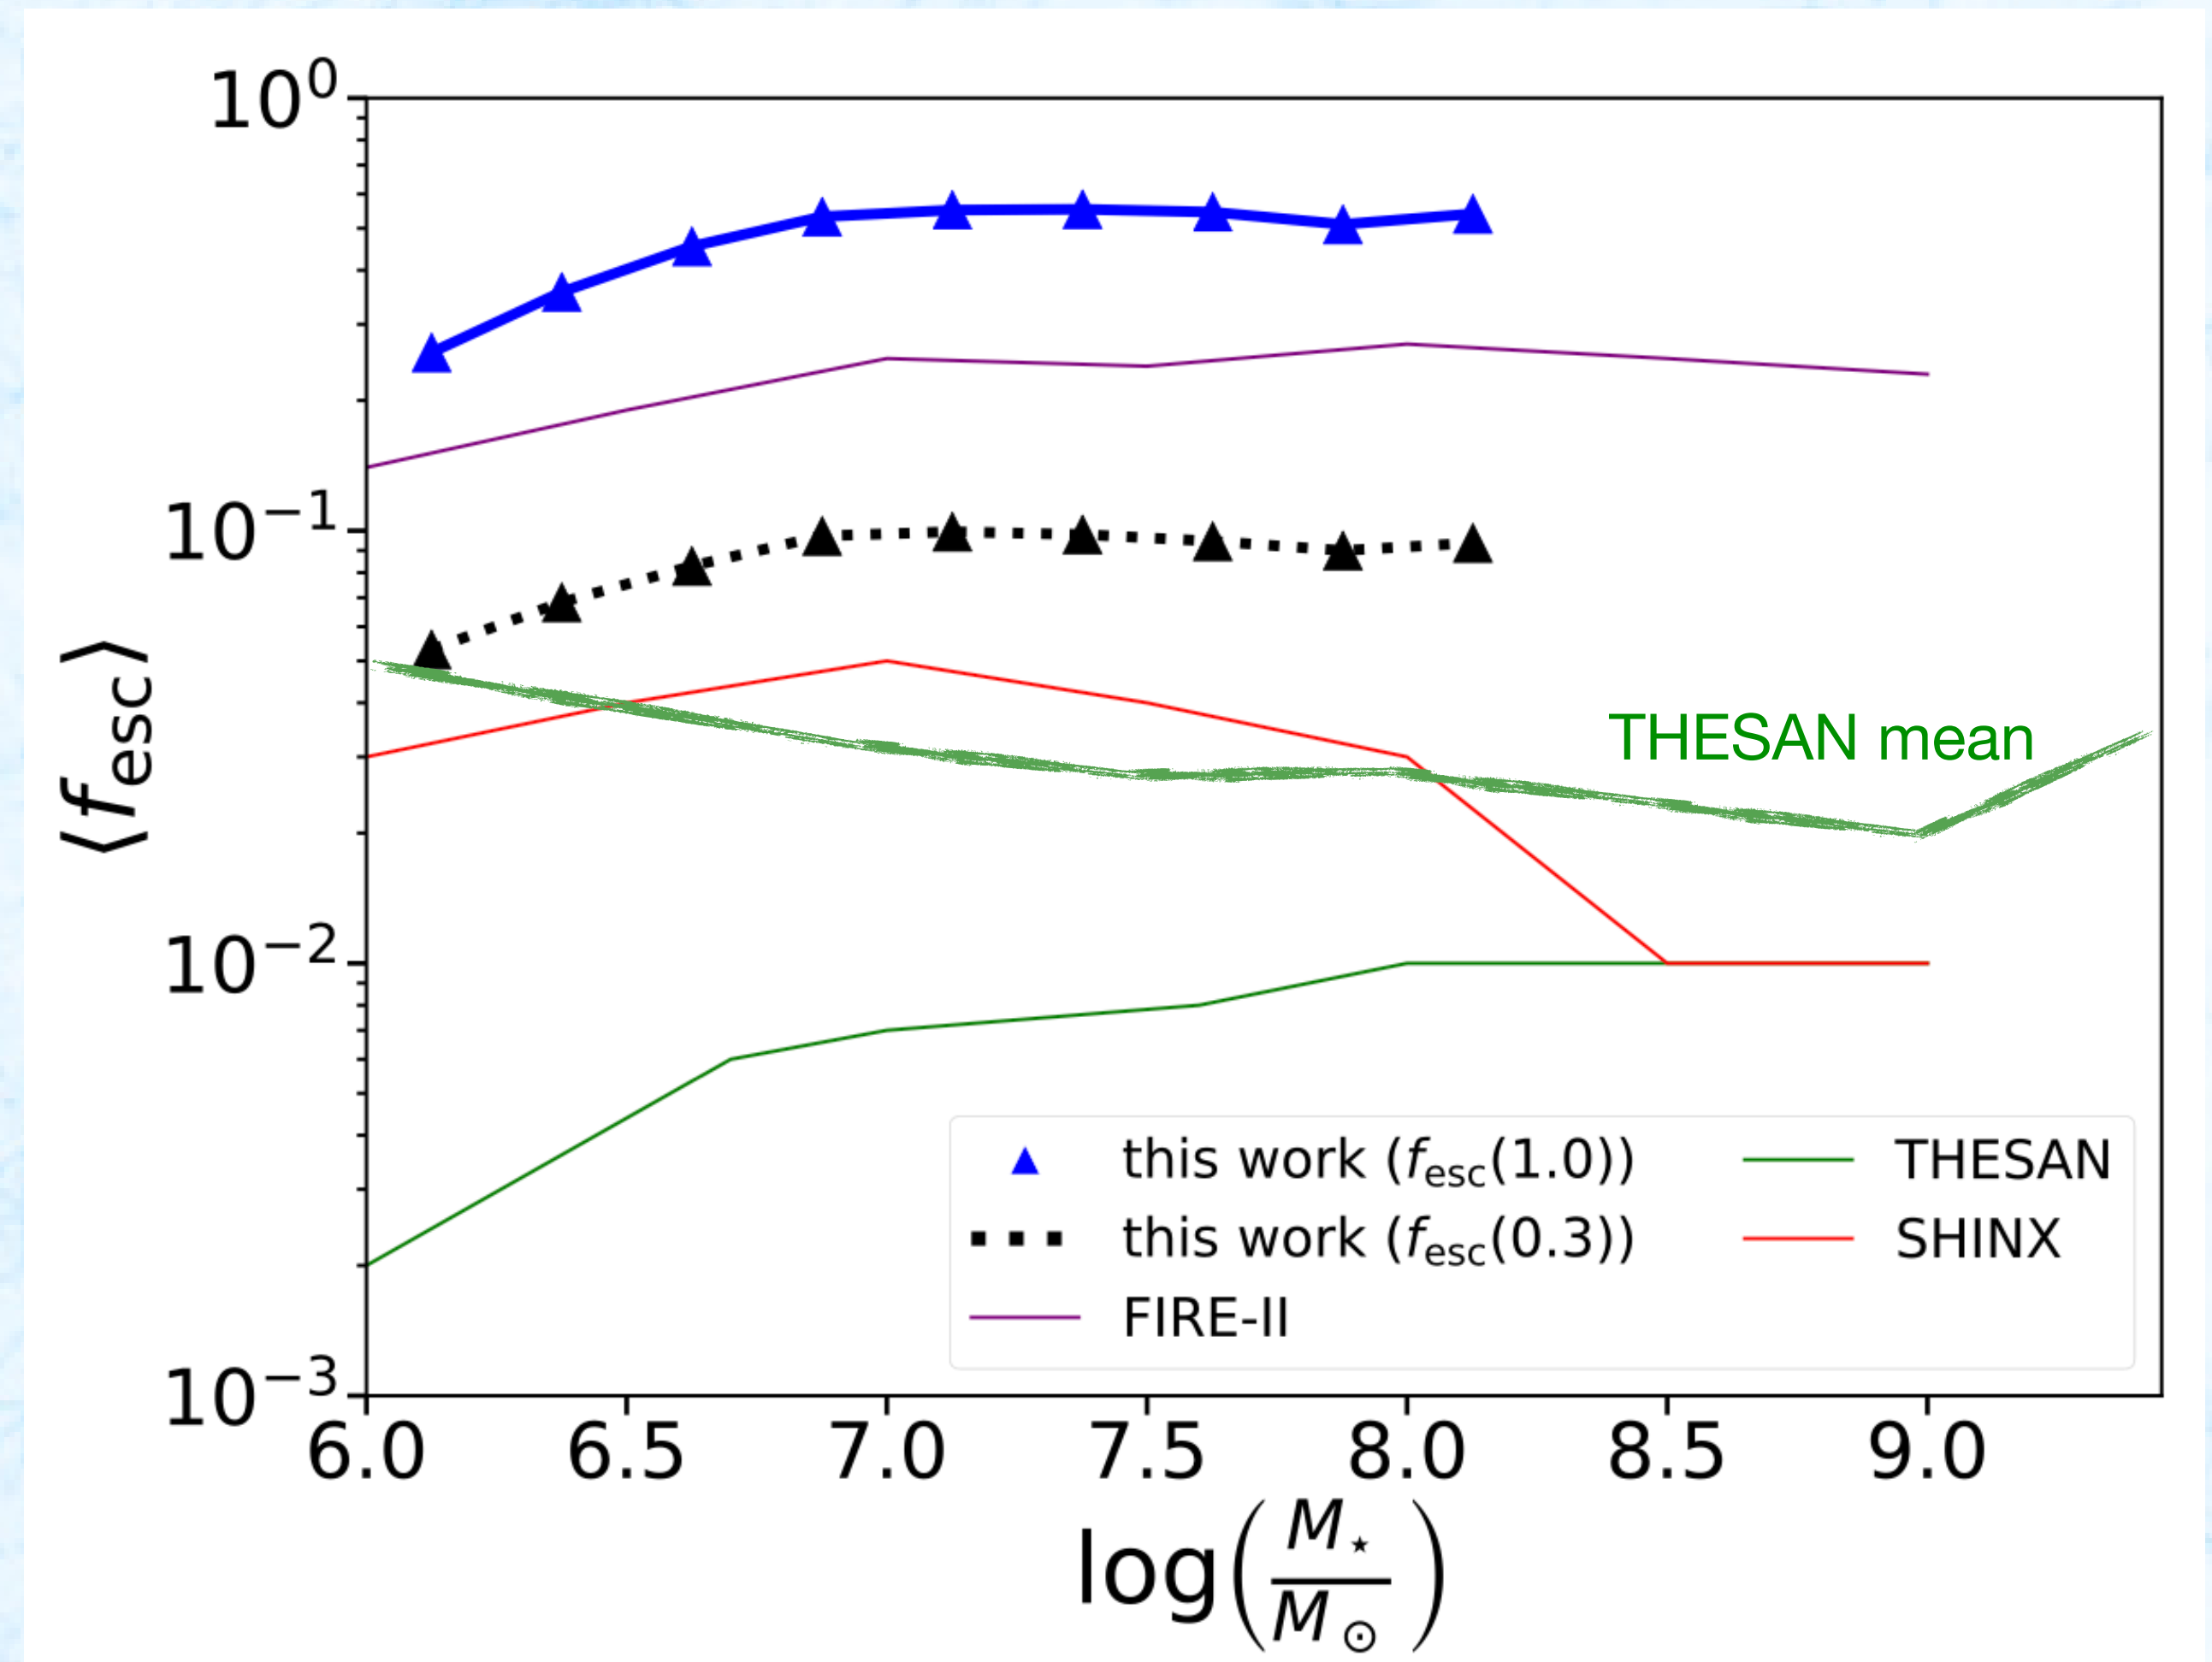

CODA, THESAN, SPHINX all produce reasonable reionization histories, UV luminosity functions, and Thomson optical depths, due to large uncertainties in observations and trade-off between SFR and  $f_{\text{esc}}$

# $f_{\text{esc}}$ vs galaxy mass

## Overview from Kostyuk+23

- Also all over the place, but
- SPHINX, FIRE, THESAN all hint at  $f_{\text{esc}}$  dropping with  $M_*$

# $f_{\text{esc}}$ vs mass in observations

Saxena+22

183 galaxies at  $z \sim 3.5$  (GOODS-S)

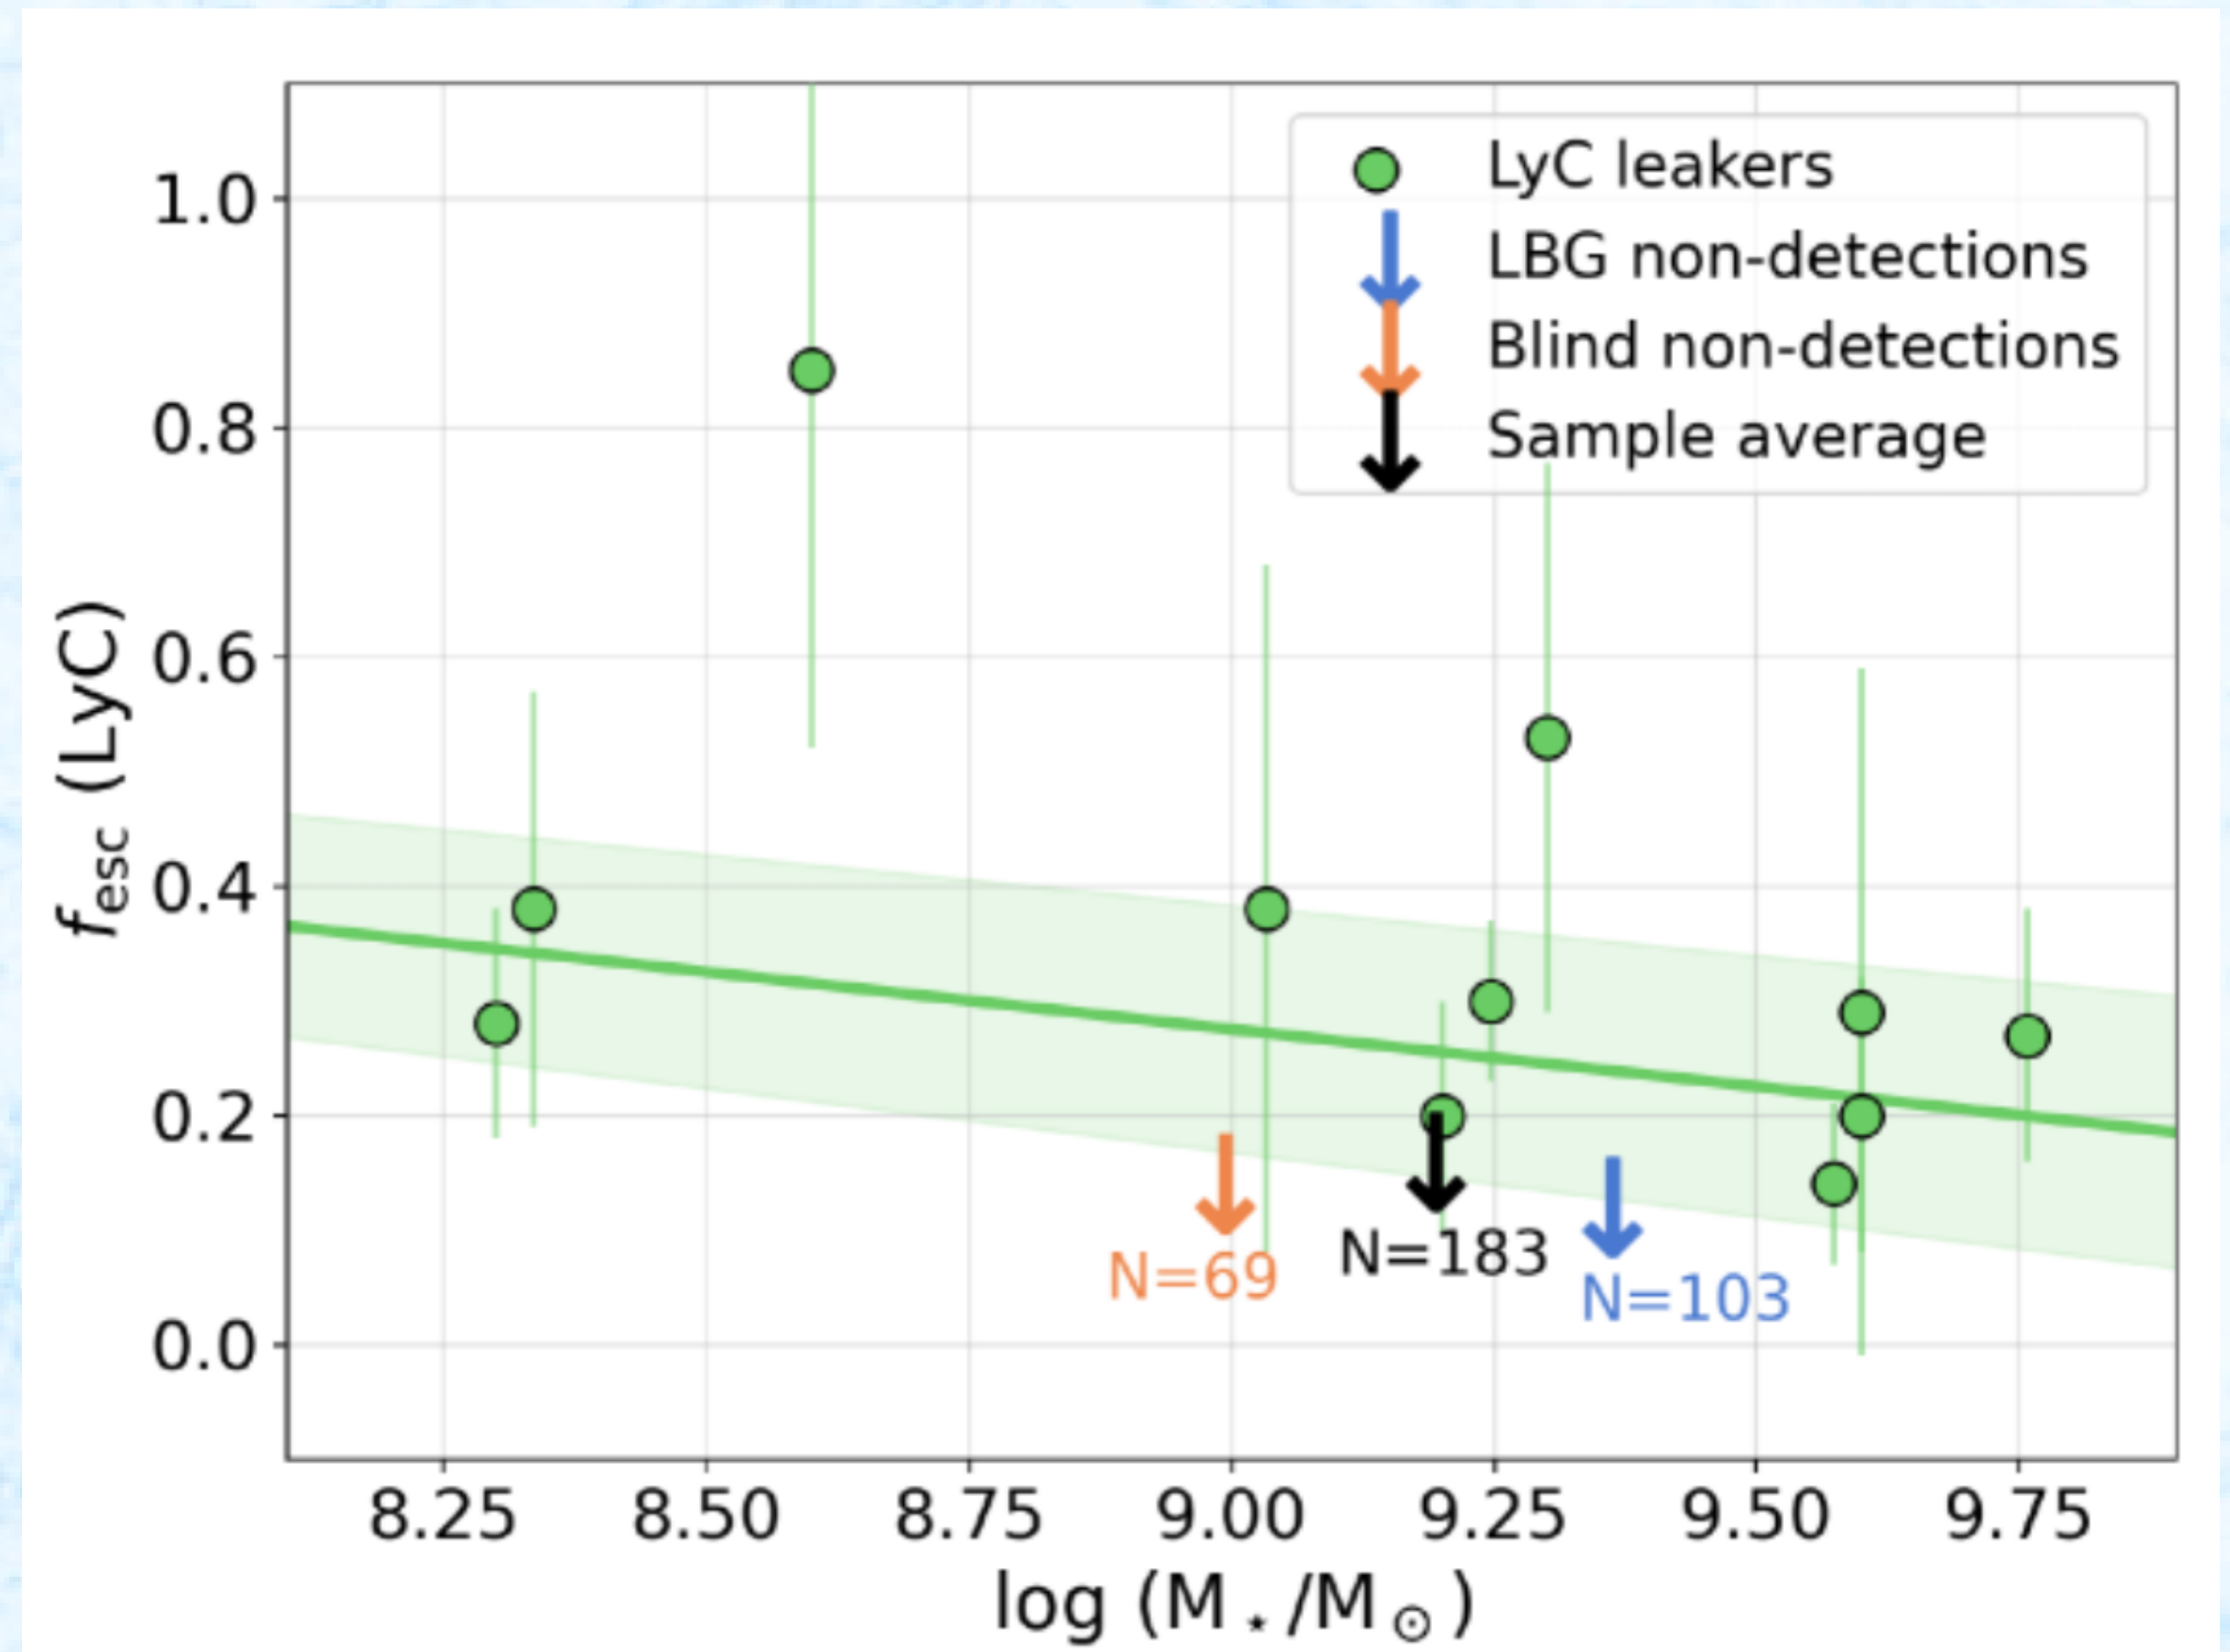

Direct LyC signals in 11 galaxies

No significant trend

But.....

- Bright and **leaking** galaxies
- Low redshift
- These are LOS escape fractions

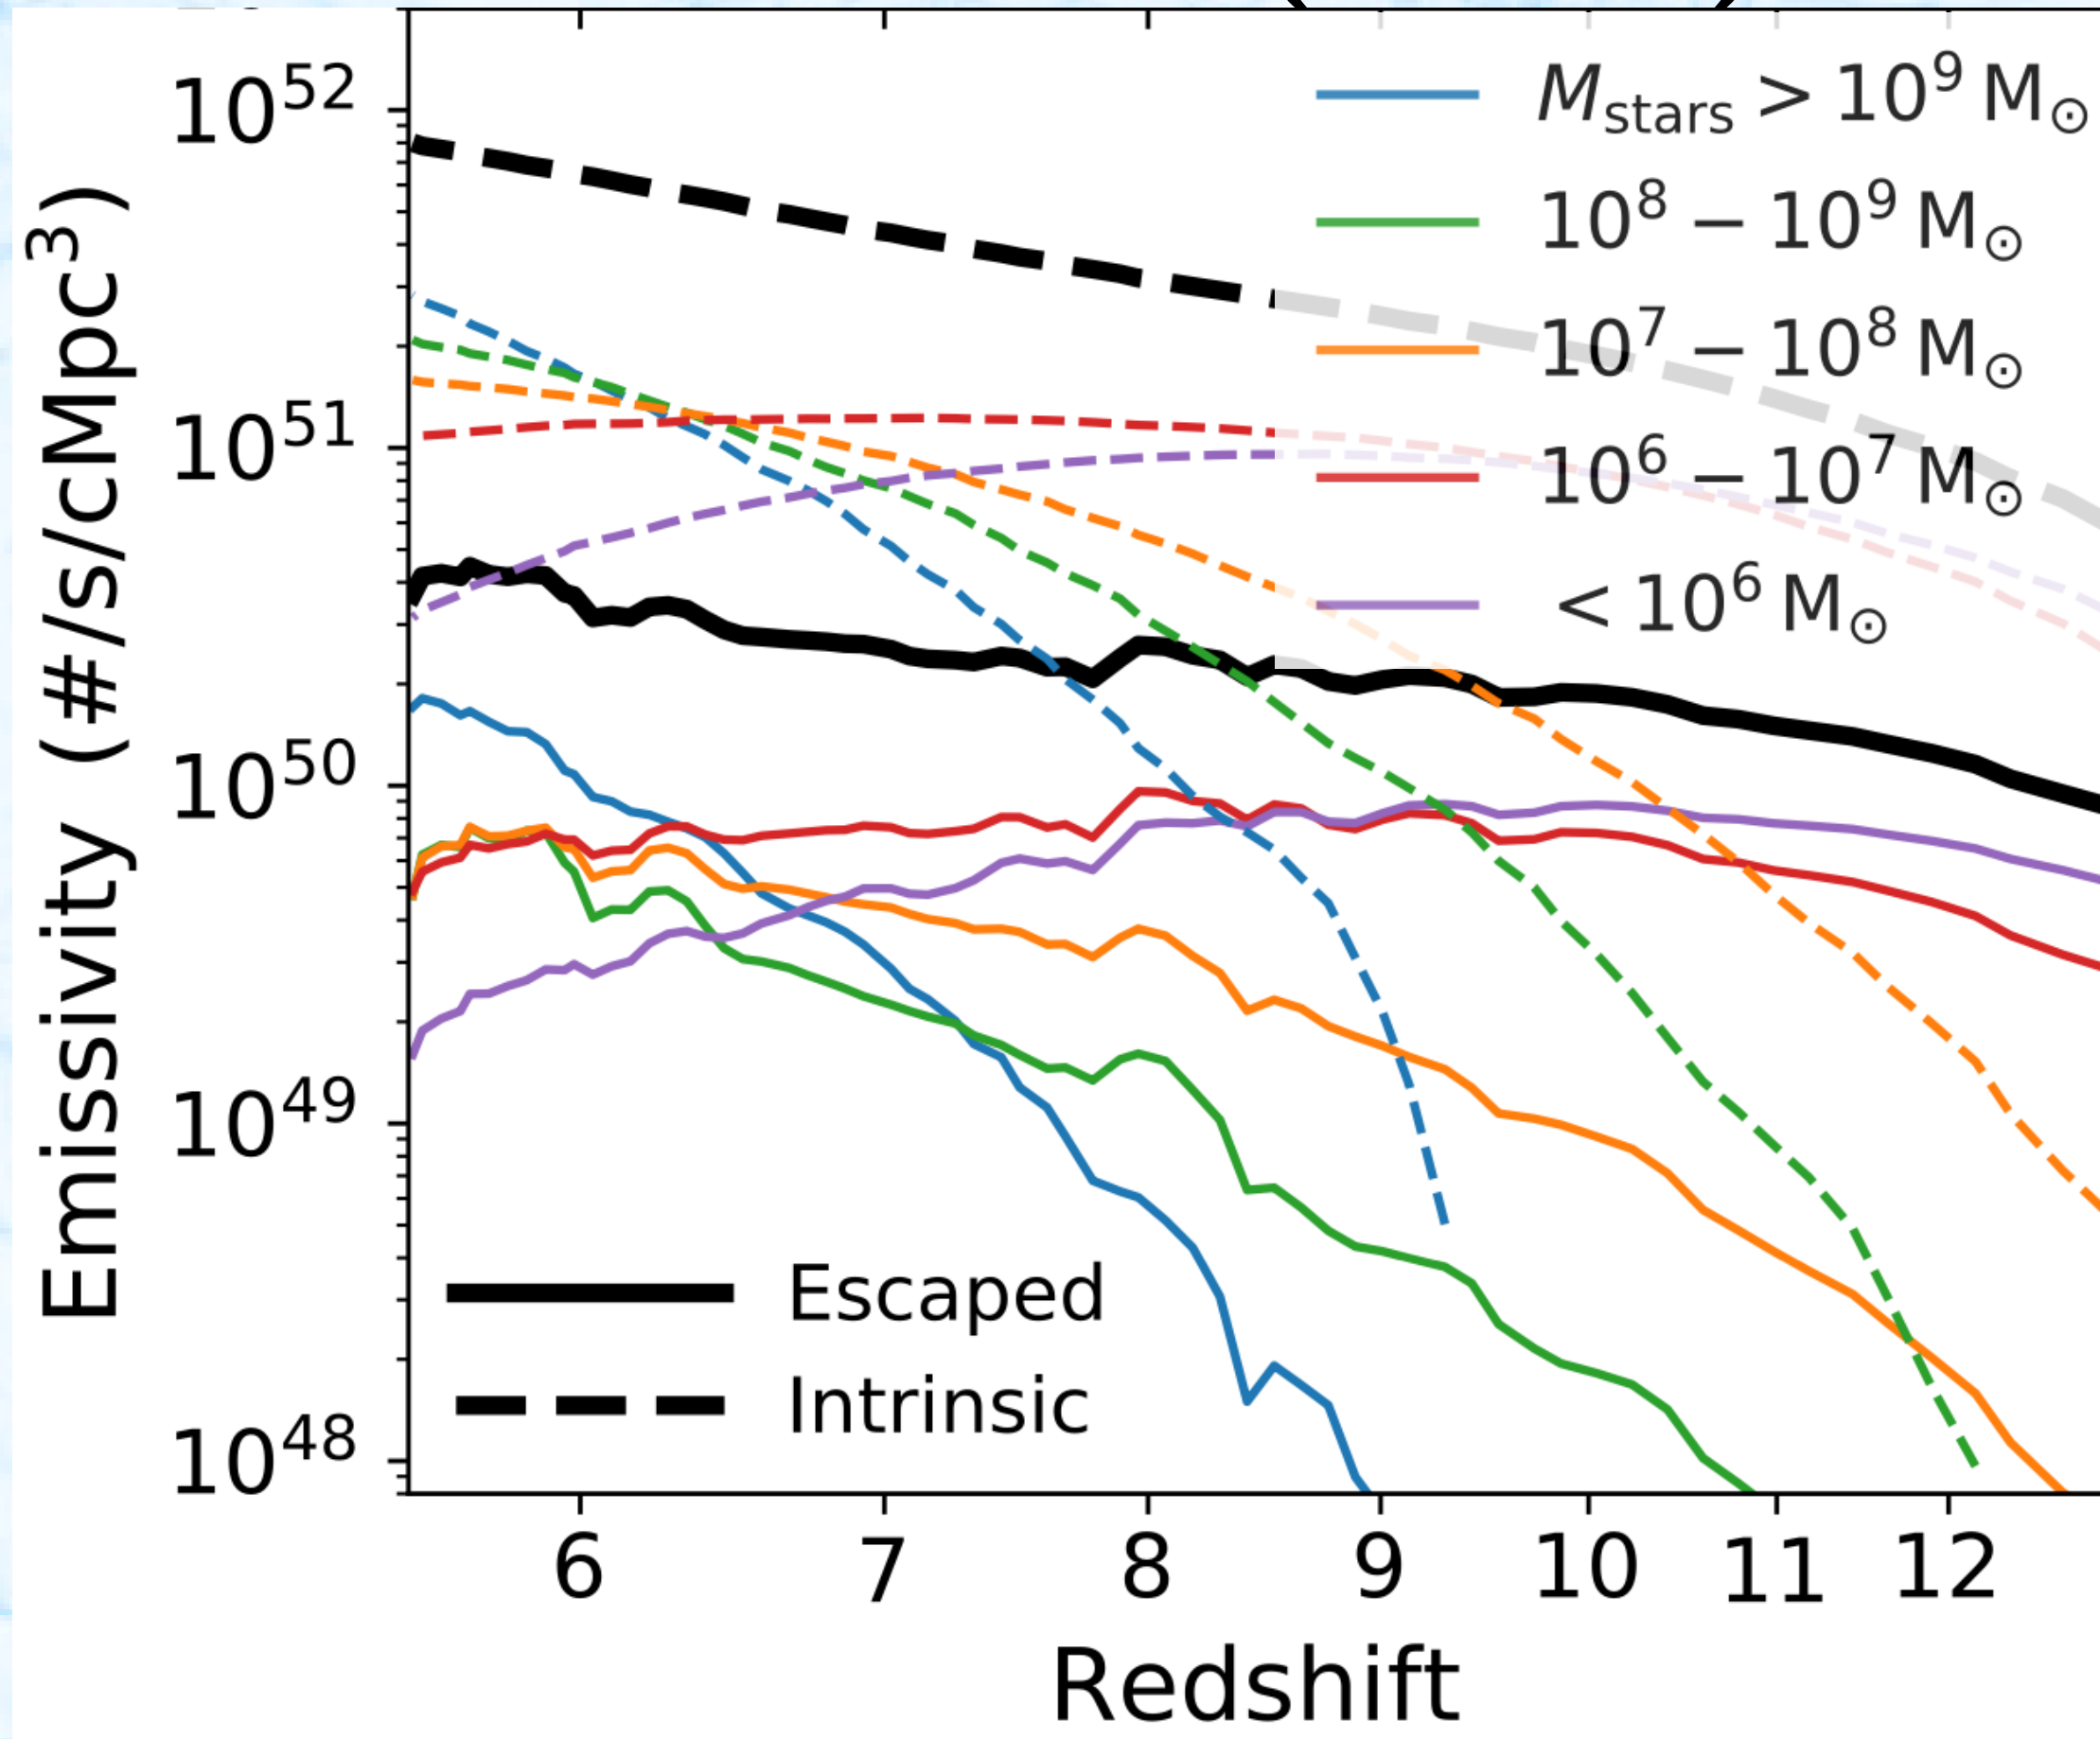

We should apply similar selections to our simulations for comparison

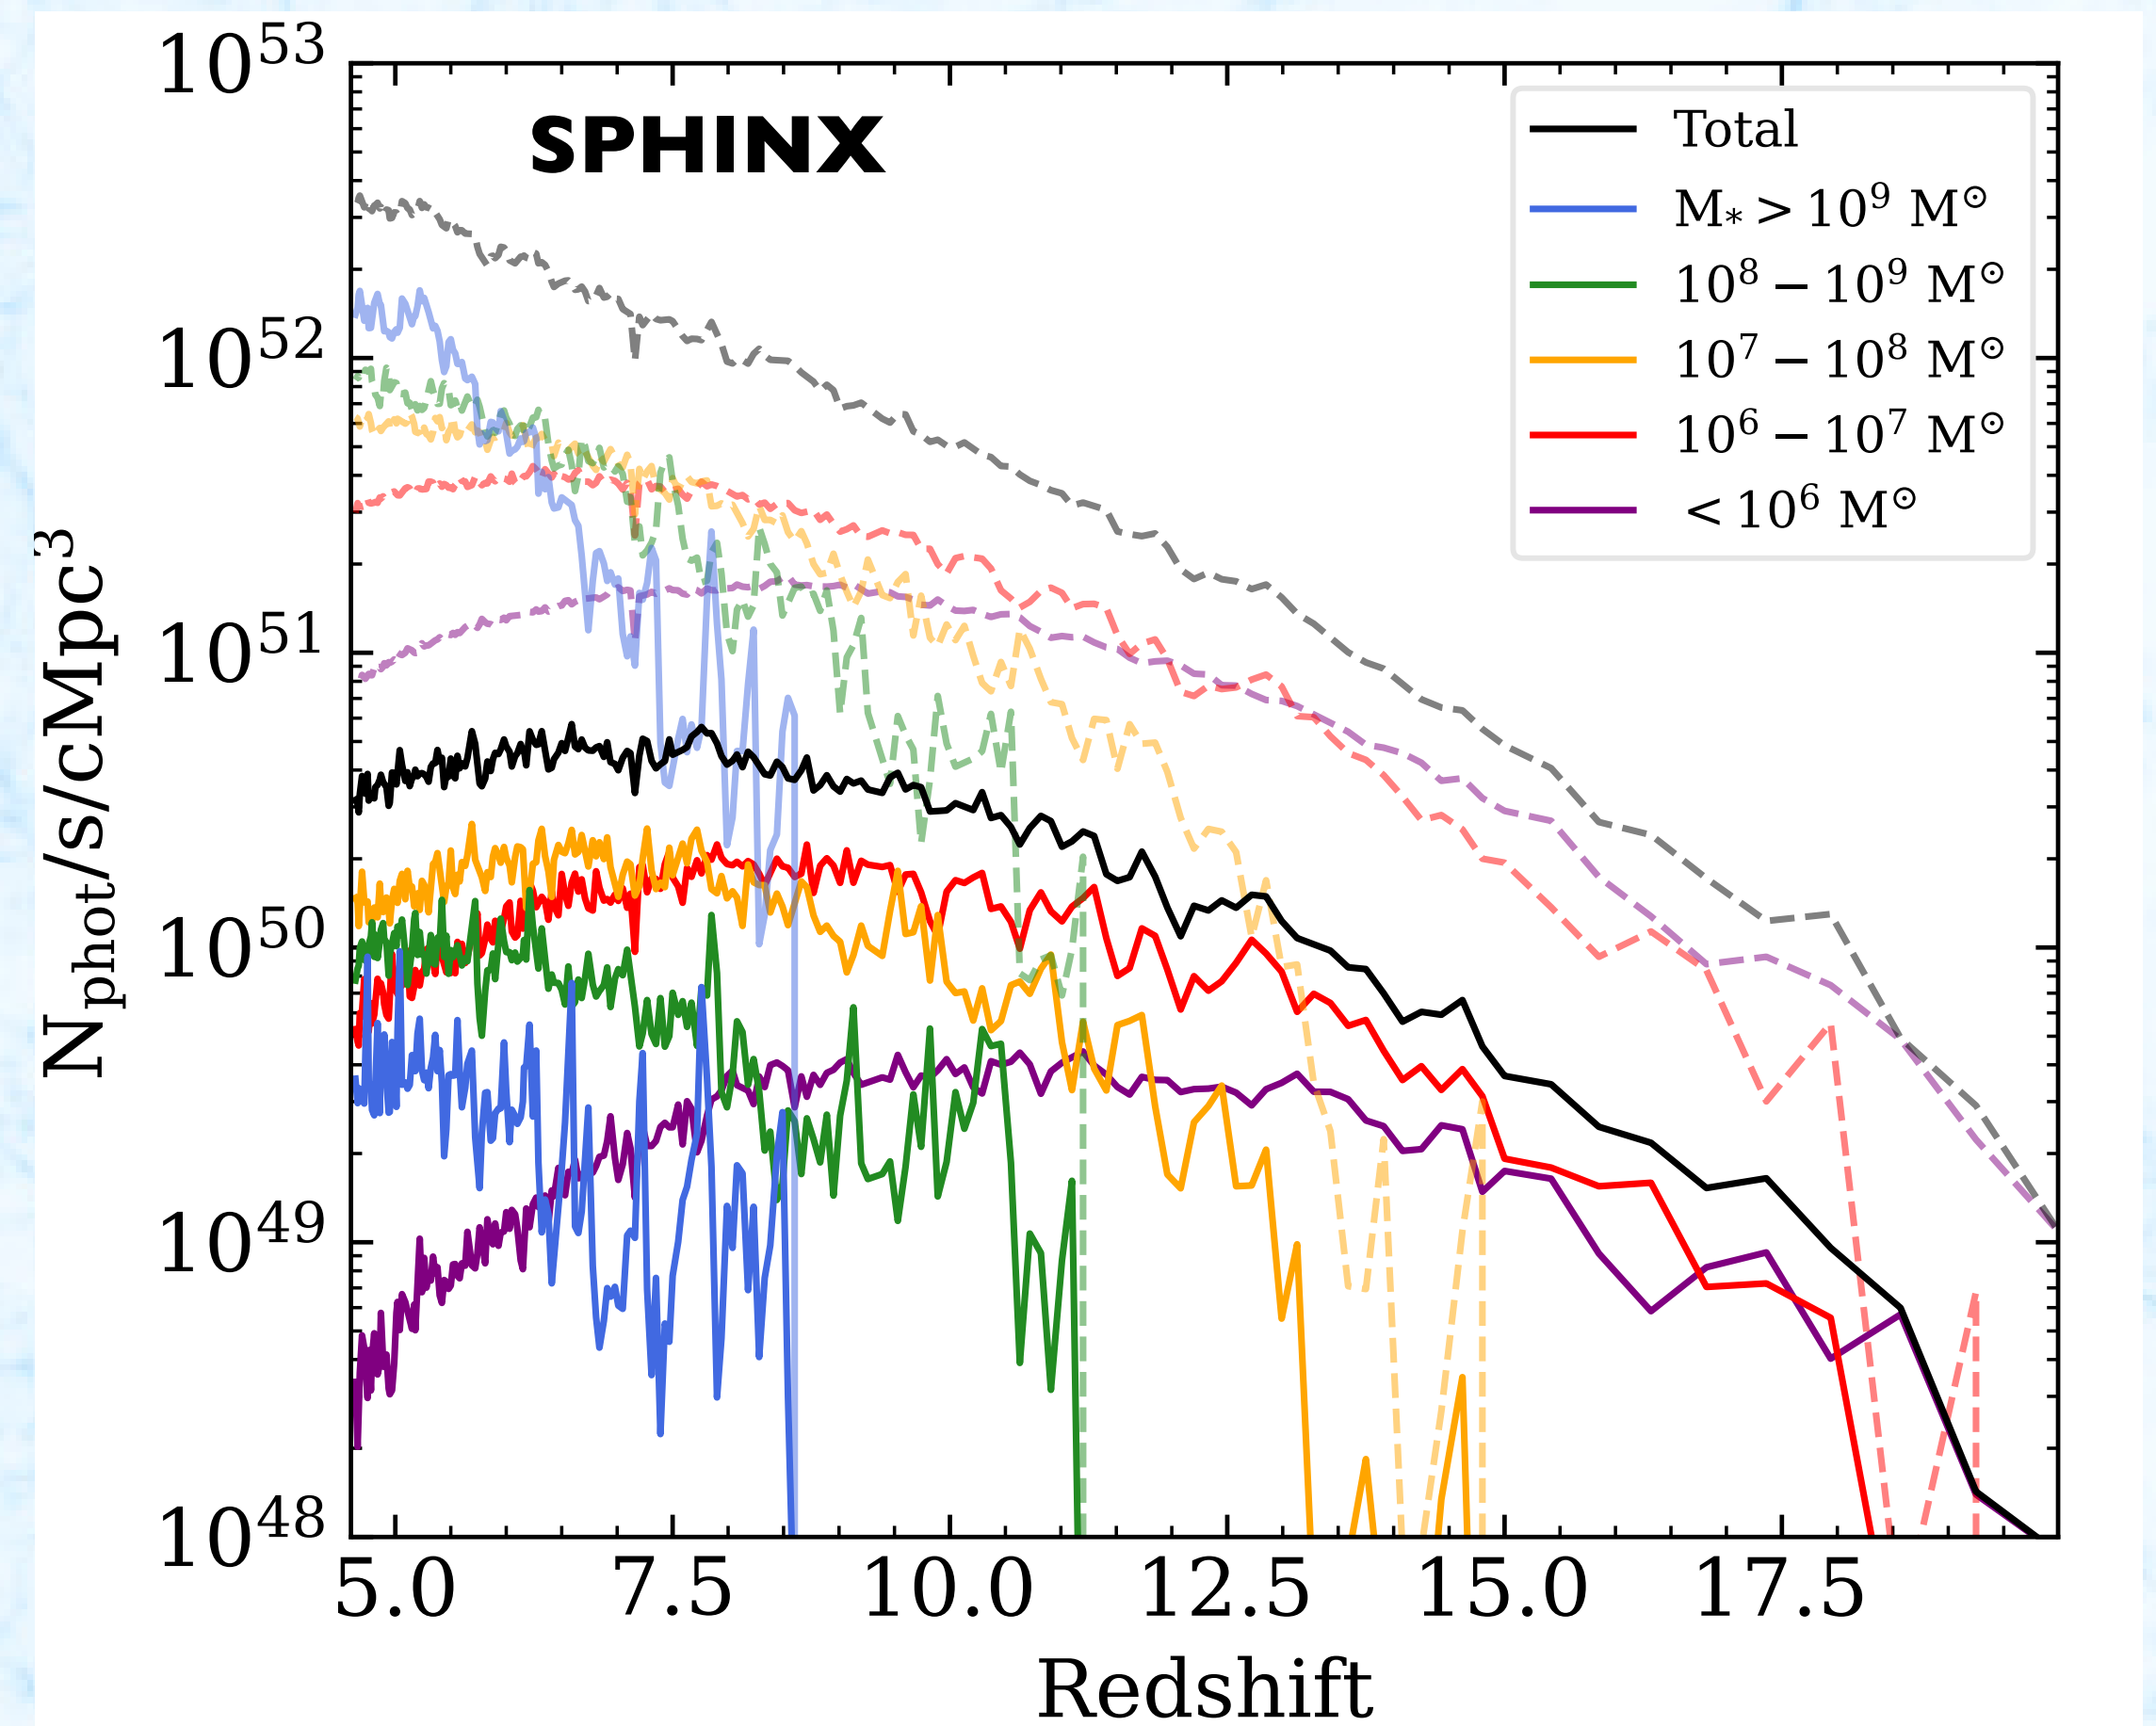

# Contributions to reionization

From Yeh+15 (THESAN)

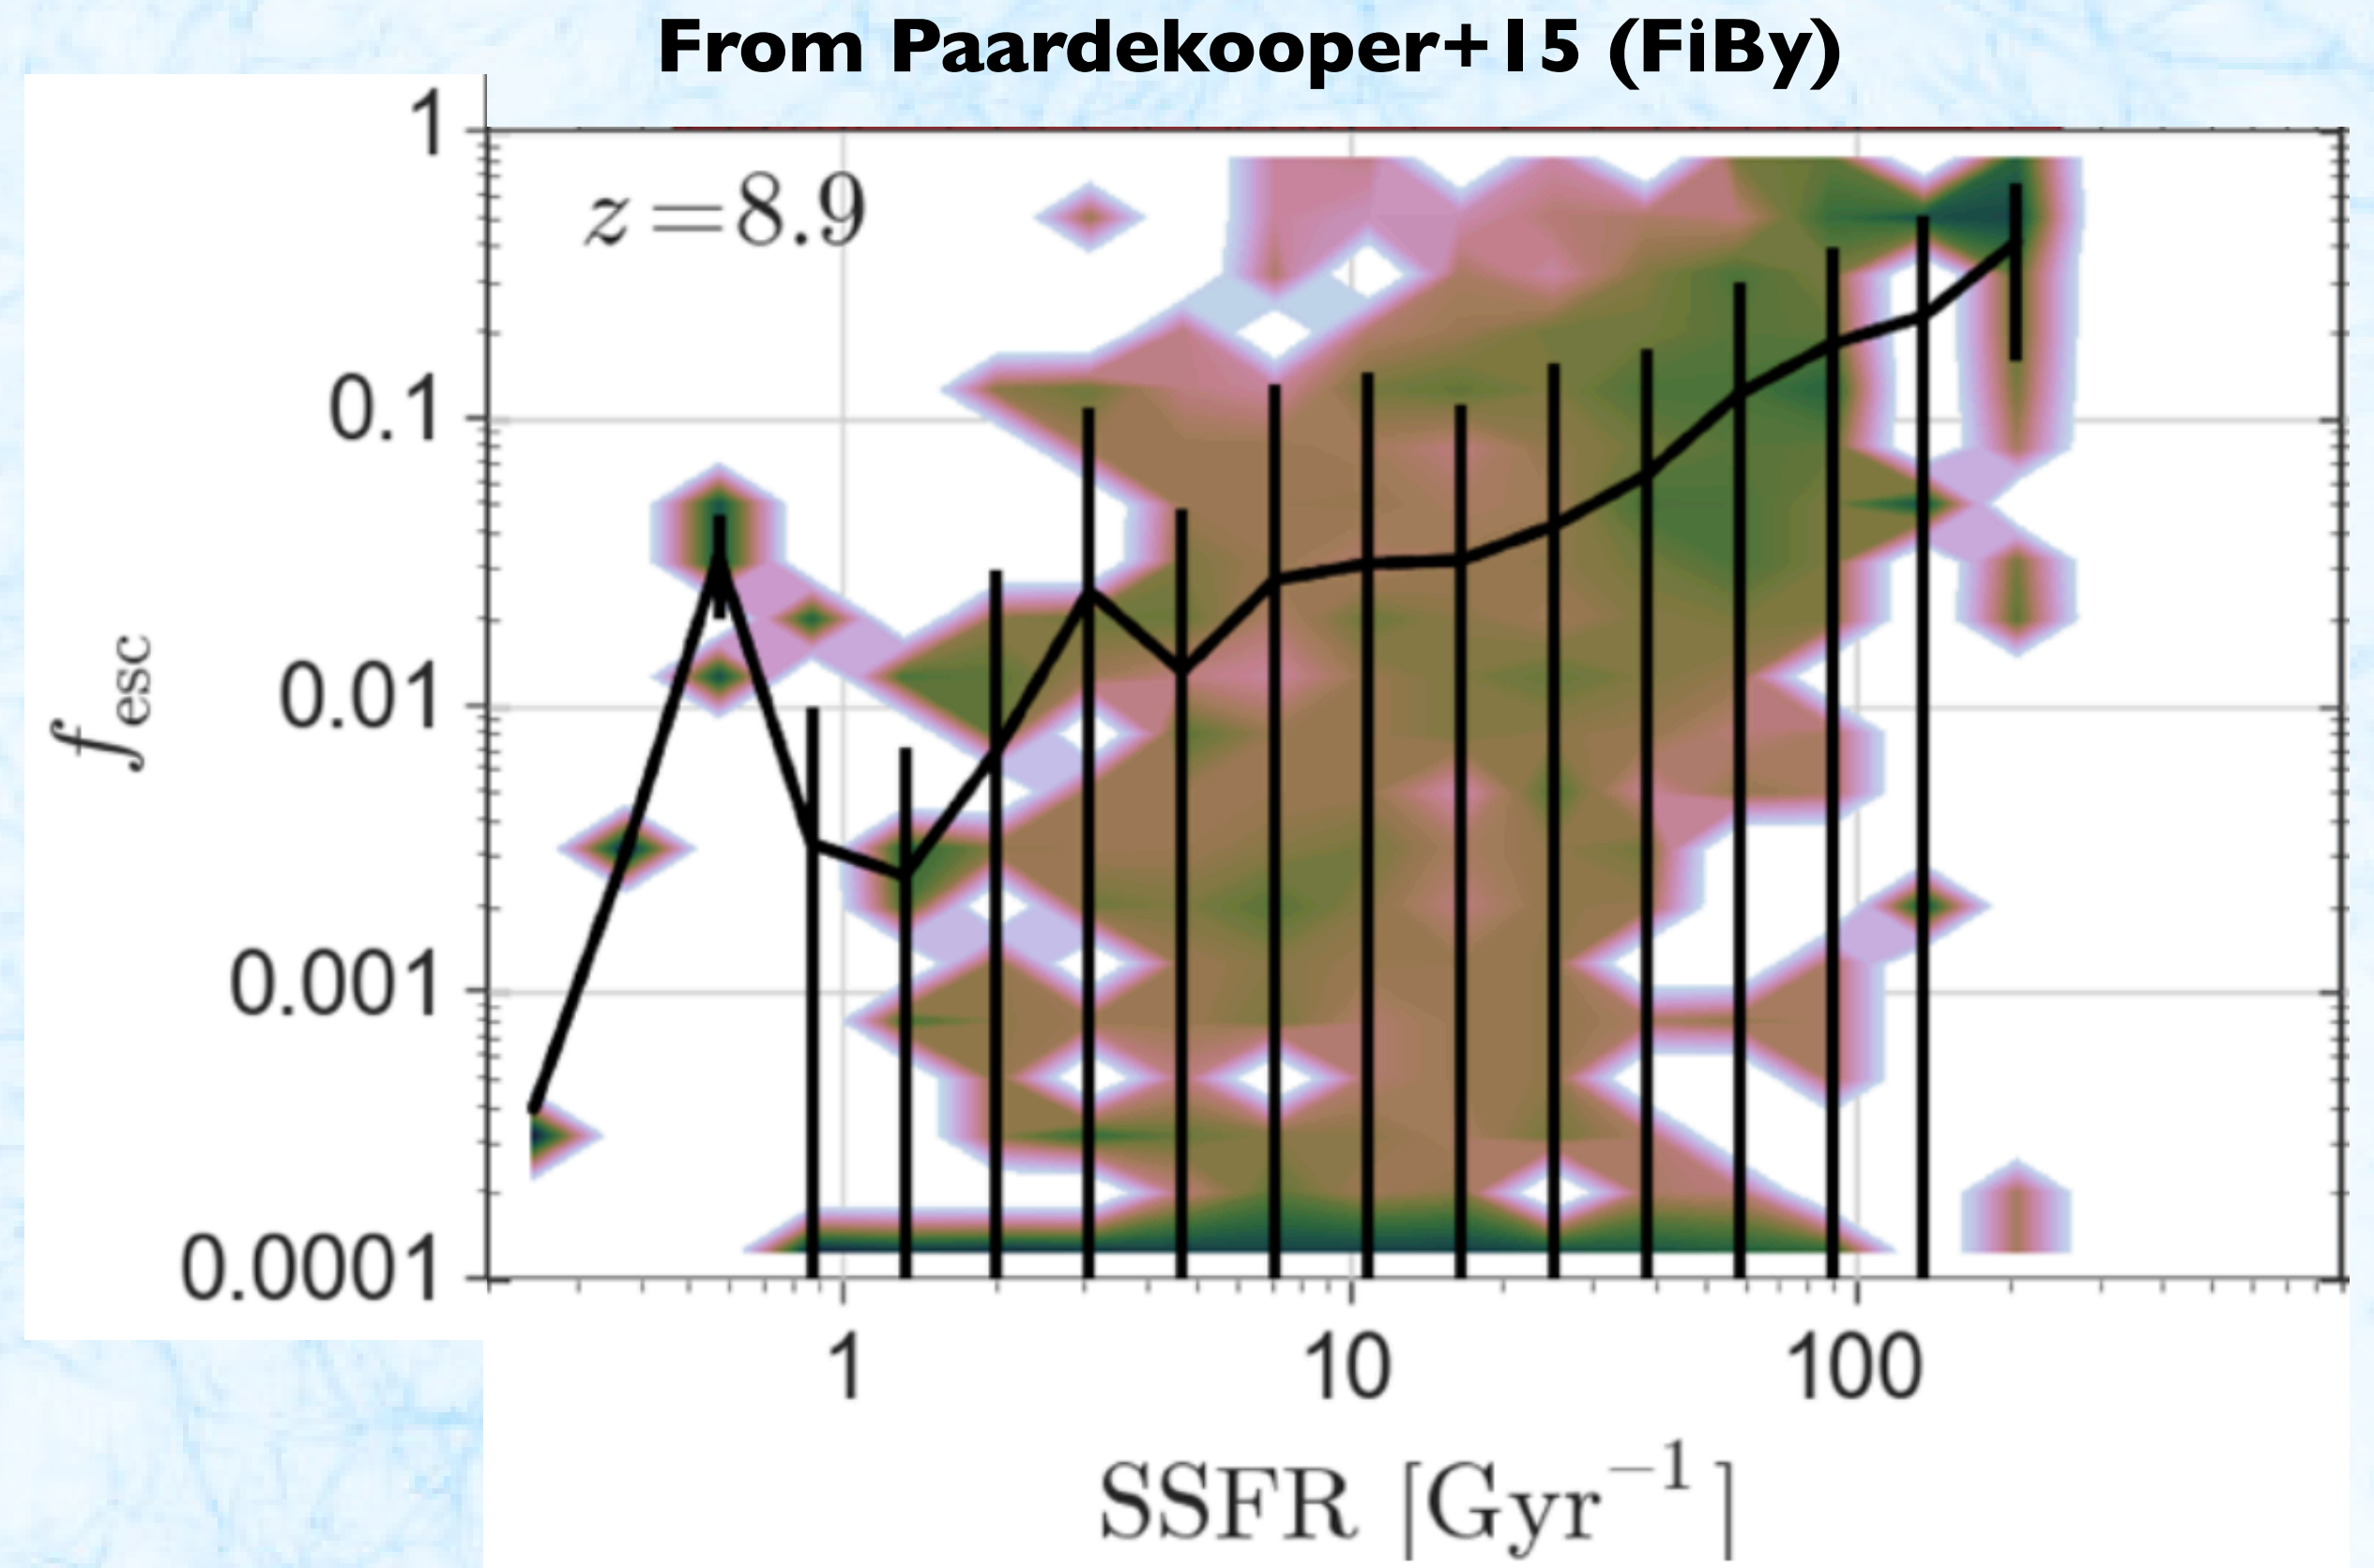

- THESAN oligarchs start to rule after  $Z \sim 6$
- SPHINX is more middle-classy
- These differences are due to different mass- $f_{\text{esc}}$  correlations

# $f_{\text{esc}}$ vs specific SFR

- $s\text{SFR} = \text{SFR}/M_*$  is a measure of star formation burstiness

- Galaxies with current or recent starbursts have high escape fractions, due to strong feedback

# Evolution of $f_{\text{esc}}$ with redshift

- Both SPHINX and THESAN find that  $f_{\text{esc}}$  decreases globally with redshift
- In SPHINX, this can be traced directly to decreasing sSFR — i.e. decreasing star formation burstiness — with redshift
- CoDa simulations find  $f_{\text{esc}}$  *increasing* with redshift

# Evolution of $f_{\text{esc}}$ with redshift

- Both SPHINX and THESAN find that  $f_{\text{esc}}$  decreases globally with redshift
- In SPHINX, this can be traced directly to decreasing sSFR — i.e. decreasing star formation burstiness — with redshift
- CoDa simulations find  $f_{\text{esc}}$  *increasing* with redshift

# $f_{\text{esc}}$ is **not** resolved in cosmological simulations

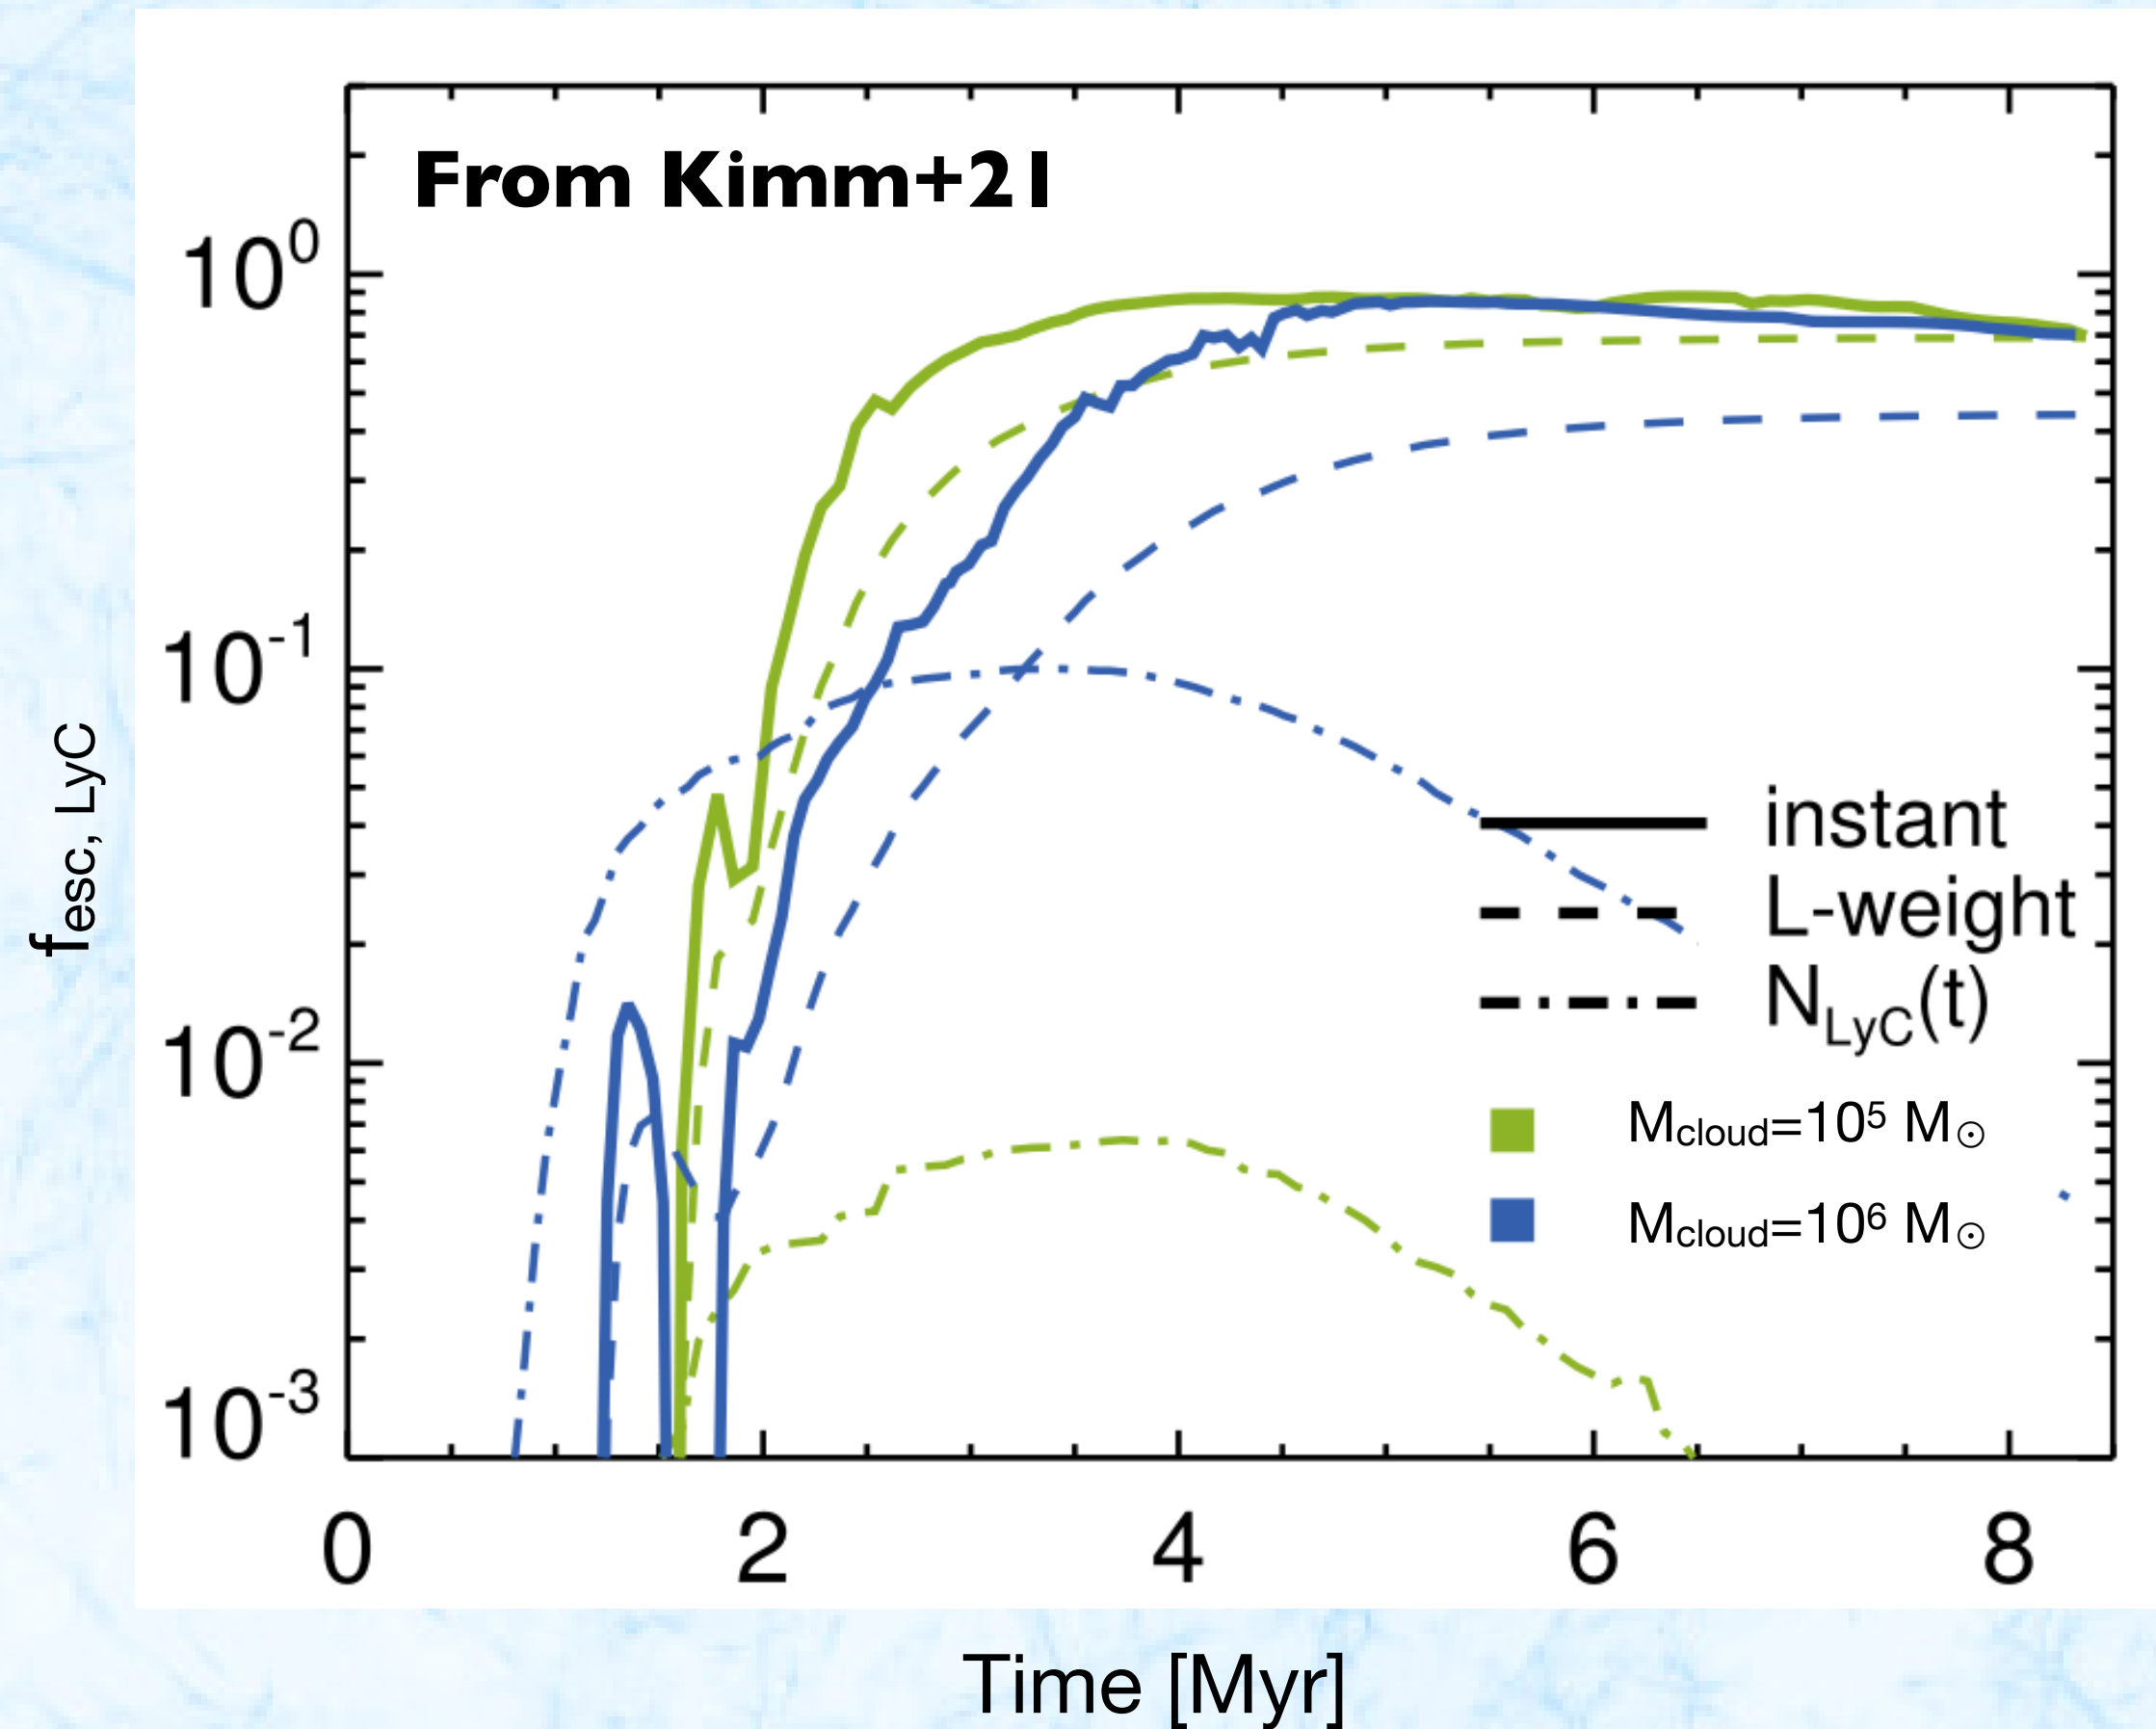

- HII regions are *mostly unresolved*, even in highest-resolution cosmological sims
- ➔ **Radiation feedback** is underestimated and likely so is  $f_{\text{esc}}$

Strömgren radius  
(where photons absorbed)

# What happens at much better resolution?

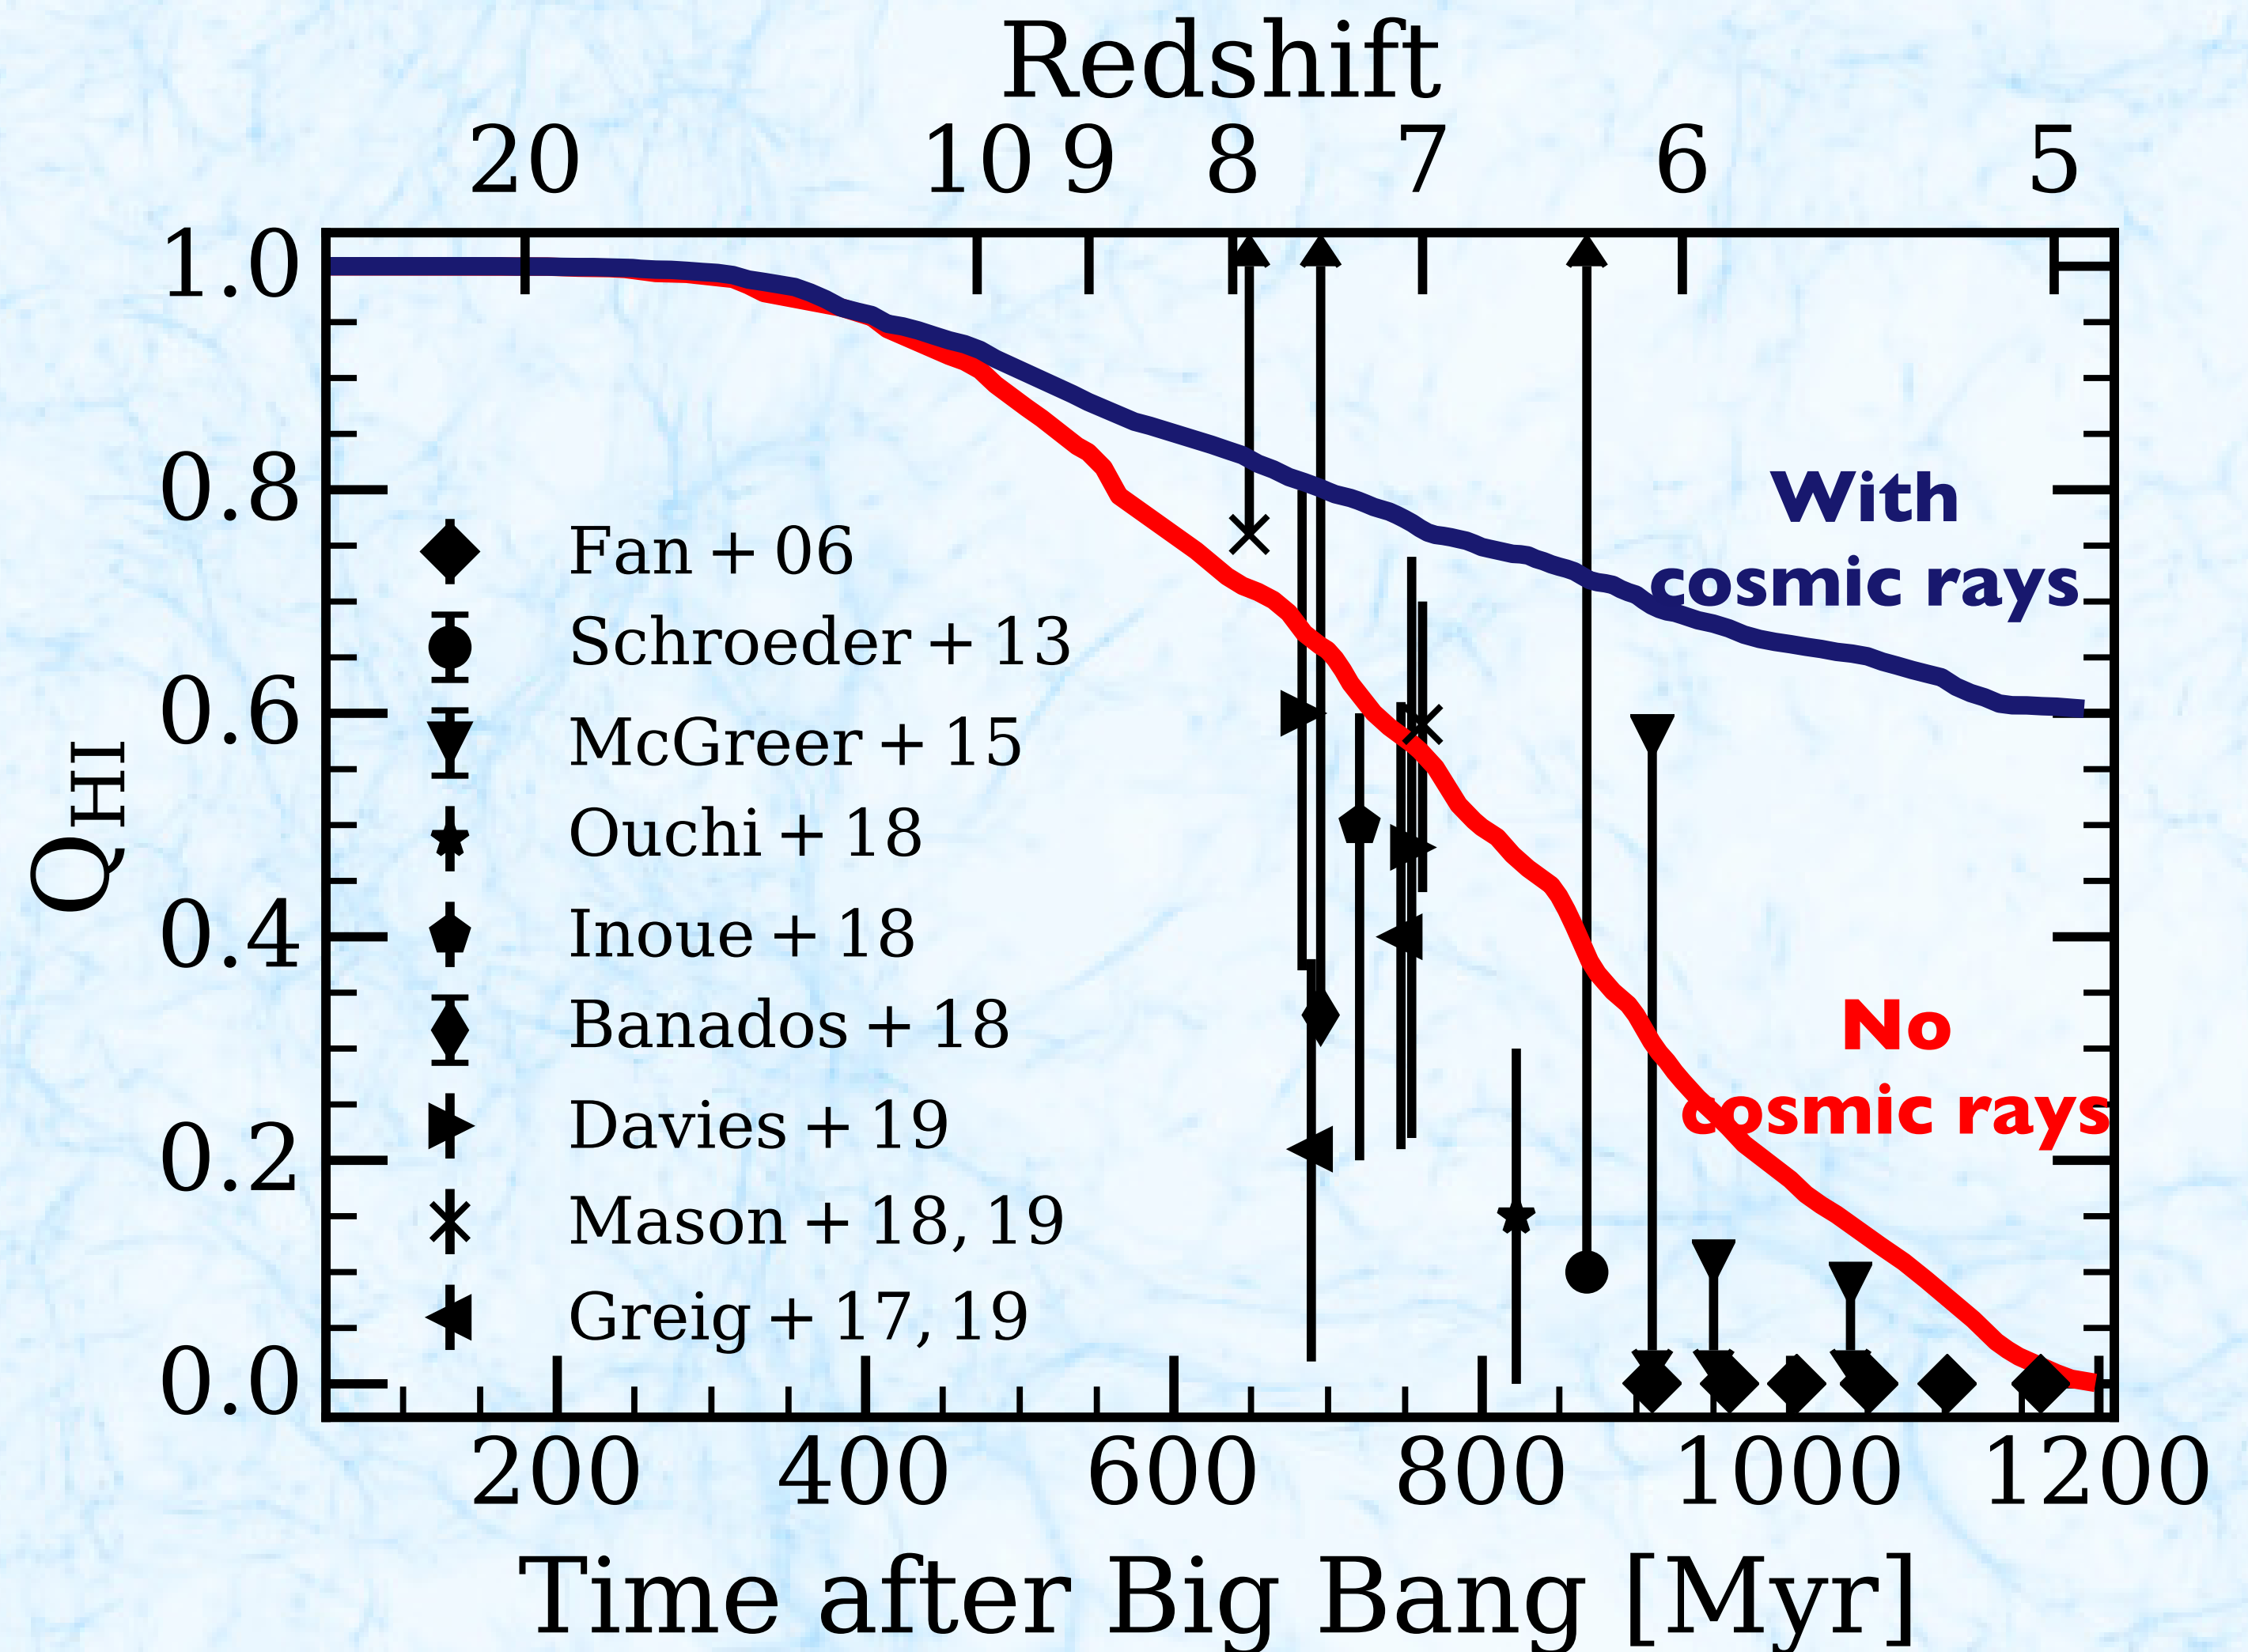

- A lot of the radiation escapes *before SN explosions, due to radiation feedback*
- We need to capture this in galaxy simulations, with sub-pc resolution and samples of thousands of galaxies!!

# Missing physics

- Cosmic rays prevent escape (Farcy)
- Stellar winds prevent escape (Geen+22)
- Magnetic fields — ?
- Stellar rotation in SEDs
- AGN (→ Yeh, Trebitsch)
- ...

Borrowed from Marion Farcy

# So are simulations useful for LyC escape?

- **At the moment they are better for increasing confusion than understanding**
- **Simulations are not very converged**
- **But it is a relatively new business to predict escape fractions**
- **With more simulations, better models and resolution, we will likely converge to something**
- **Also, this talk was quite narrowly about LyC escape and simulations are very useful in many aspects for reionization**
  - **SPHINX and THESAN data releases are surely useful to many of you (mock observables, SFHs, escape fractions, ...)**
